Hopf algebras of dimension $2p^2$

Michael Hilgemann and Siu-Hung Ng

Dedicated to Susan Montgomery on the occasion of her birthday

Abstract

Let $H$ be a non-semisimple Hopf algebra of dimension $2p^2$ over an algebraically closed field $k$ of characteristic zero, where $p$ is an odd prime. We prove that $H$ or $H^*$ is pointed, which completes the classification for Hopf algebras of these dimensions.

Introduction

In recent years, there have been some developments in the classification of finite-dimensional Hopf algebras over an algebraically closed field $k$ of characteristic zero. For a prime $p$, Hopf algebras of dimension $p$ were shown by Zhu [34] to be isomorphic to the group algebra $k[Z_p]$. Hopf algebras of dimension $p^2$ were completely classified in [13, 20]. In the semisimple case, they are isomorphic to either $k[Z_{p^2}]$ or $k[Z_p \times Z_p]$, and, in the non-semisimple case, they are the Taft algebras of dimension $p^2$.

Semisimple Hopf algebras of dimension $pq$, where $p$ and $q$ are distinct primes, were first classified by Masuoka [12] for the case $p = 2$. For both $p$ and $q$ odd, they were studied independently in [8, 31]. It was proved by Etingof and Gelaki [4] that these Hopf algebras must be trivial, that is, they are isomorphic to group algebras or the duals of group algebras.

It is, in general, an open question as to whether every Hopf algebra over $k$ of dimension $pq$, where $p$ and $q$ are distinct primes, is semisimple. However, there have been some partial results that suggest an affirmative answer to the question. Natale showed that a quasi-triangular Hopf algebra of such a dimension is semisimple in [18]. In [22, 23], the second author proved that there is no non-semisimple Hopf algebra of dimension $2p$ for an odd prime $p$, or of dimension $pq$ with $2 < p < q \leq 4p + 11$. The latter improves the main results in [5, 21].

These established classifications have provided a foundation for the investigation of a general Hopf algebra over $k$ whose dimension is a product of two primes. The study of Hopf algebras of dimension $p^3$ was carried out by García [7]. In this paper, we address Hopf algebras of dimension $2p^2$ for an odd prime $p$.

Masuoka began the classification of semisimple Hopf algebras of dimension $2p^2$ in [14]. In the paper, he constructed a semisimple Hopf algebra $B_0$ (denoted by $A_3$ in that paper) of dimension $2p^2$, which he showed is the unique semisimple Hopf algebra $H$ of such a dimension with $|G(H)| = p^2$. Natale completed the classification in [17] by showing that non-trivial semisimple Hopf algebras of dimension $2p^2$ are isomorphic to $B_0$ or $B_0^*$. Since $G(B_0^*) \cong \mathbb{Z}_{2p}$, it follows that $B_0$ is not self-dual.

The Hopf algebra $B_0^*$ is a smash product Hopf algebra $k[D_{2p}]^* \# k[Z_p]$, where $D_{2p}$ is the dihedral group of order $2p$ (cf. [17]). The left $k[Z_p]$-action on $k[D_{2p}]^*$ is induced by the right
action $\triangleright$ of $\mathbb{Z}_p = \langle g \rangle$ on $D_2p = \langle a, b \mid b^p = 1, a^2 = 1, aba = b^{-1} \rangle$ as automorphisms given by
\[ b \triangleright g = b, \quad a \triangleright g = ba. \]

For the case that $H$ is a pointed non-semisimple Hopf algebra of dimension $2p^2$, it was shown by Andruskiewitsch and Natale [1] that $H$ is isomorphic to one of the four types of Hopf algebras listed in Lemma A.1 of that paper. Specifically, let $j \in \{1, 2, 4, \ldots, 2p - 2\}$ and $\mu \in \{0, 1\}$ such that $\mu = 0$ whenever $j \neq 1$. Also let $\tau \in \kappa$ be a $2p$th root of unity such that the order of $\tau$ is a multiple of $p$, with the order being $p$ in the case that $j = 1$. Define $A(\tau, j, \mu)$ to be the Hopf algebra generated by the elements $g$ and $x$ as an algebra subject to the relations
\[ g^{2p} = 1, \quad x^p = \mu(1 - g^p), \quad gx = \tau xg, \]
with comultiplication given by
\[ \Delta(g) = g \otimes g, \quad \Delta(x) = x \otimes 1 + g^j \otimes x. \]

Then the pointed non-semisimple Hopf algebras of dimension $2p^2$ are isomorphic to exactly one of the following $4(p - 1)$ Hopf algebras:

(i) $A(\omega, 1, 0)$, where $\omega$ is a primitive $p$th root of unity;

(ii) $A(\omega, 1, 1)$, where $\omega$ is a primitive $p$th root of unity;

(iii) $A(\tau, 2r, 0)$, for $1 \leq r < p - 1$, where $\tau$ is a fixed primitive $2p$th root of unity;

(iv) $A(\omega, 2, 0) \cong T_p \otimes \kappa[\mathbb{Z}_2]$, where $\omega$ is a primitive $p$th root of unity.

Here $T_p$ is a Taft algebra of dimension $p^2$. It was pointed out in [1] that the dual of $A(\omega, 1, 0)$ is isomorphic to a Hopf algebra of type (iii), and the Hopf algebras of type (iv) are self-dual. Therefore, the dual of a Hopf algebra of type (i), (iii), or (iv) is also pointed. However, the dual of $A(\omega, 1, 1)$ is not pointed (cf. [25]).

In [6], Fukuda showed that non-semisimple Hopf algebras of dimension 18 are pointed or have a pointed dual. In this paper, we complete the classification of Hopf algebras of dimension $2p^2$ by proving the following main theorem.

**Theorem I.** If $H$ is a non-semisimple Hopf algebra of dimension $2p^2$ over an algebraically closed field of characteristic zero, where $p$ is an odd prime, then $H$ or $H^*$ is pointed.

In particular, this implies that there are exactly $5(p - 1)$ isomorphism classes of non-semisimple Hopf algebras of dimension $2p^2$ over $\kappa$, and we summarize the classification as follows.

**Theorem II.** Let $H$ be a $2p^2$-dimensional Hopf algebra over an algebraically closed field $\kappa$ of characteristic zero, where $p$ is an odd prime. Then one of the following holds:

(a) $H$ is trivial;

(b) $H$ is non-trivial and semisimple, and hence isomorphic to either $B_0$ or $B_0^*$;

(c) $H$ is non-semisimple and pointed, and hence $H$ is isomorphic to one of the $4(p - 1)$ Hopf algebras of the form $A(\omega, 1, 0)$, $A(\omega, 1, 1)$, $A(\tau, 2r, 0)$, or $A(\omega, 2, 0)$, as described above;

(d) $H$ is neither semisimple nor pointed. In this case, $H \cong A(\omega, 1, 1)^*$ for some primitive $p$th root of unity $\omega \in \kappa$.

The remainder of this paper is organized as follows. We start in Section 1 with some notation and preliminary results that will be useful in proving the main theorem. We show in Section 2 that a non-semisimple Hopf algebra of dimension $2p^2$ over an algebraically closed field $\kappa$ must have an antipode of order $2p$. Finally, in Section 3, we complete the classification of Hopf
algebras of dimension $2p^2$ by showing that non-semisimple Hopf algebras of these dimensions are pointed or have a dual that is pointed.

Throughout this paper, $k$ denotes an algebraically closed field of characteristic zero unless specifically stated otherwise. The tensor product $\otimes_k$ will be simply denoted by $\otimes$. The readers are referred to [15, 32] for elementary properties of Hopf algebras.

1. Notation and preliminaries

Let $H$ be a finite-dimensional Hopf algebra over $k$ with comultiplication $\Delta$, counit $\epsilon$, and antipode $S$. We use Sweedler’s notation for comultiplication, $\Delta(h) = \sum_{(h)} h_1 \otimes h_2$, or simply $\Delta(h) = h_1 \otimes h_2$, suppressing the summation. The coassociativity of $\Delta$ induces two natural $H^*$-actions, $\rightarrow$ and $\leftarrow$, on $H$ given by
\[ f \mapsto h = \sum_{(h)} h_1 f(h_2) \quad \text{and} \quad h \leftarrow f = \sum_{(h)} f(h_1)h_2 \quad \text{for} \quad h \in H, f \in H^*. \]

A left integral of $H$ is an element $\Lambda \in H$ such that $h\Lambda = \epsilon(h)\Lambda$, and a right integral of $H$ can be defined similarly. The subspace of the left (or right) integrals of $H$ is always one-dimensional. One can easily see that an element $\lambda \in H^*$ is a right integral if and only if
\[ h \leftarrow \lambda = \lambda(h)1_H \quad \text{for all} \quad h \in H. \] (1.1)

A non-zero element $a \in H$ is said to be group-like if $\Delta(a) = a \otimes a$. The set of all group-like elements of $H$, denoted by $G(H)$, forms a group under the multiplication of $H$, and is linearly independent over $k$. The distinguished group-like elements $g \in G(H)$ and $\alpha \in G(H^*)$ are defined by the conditions:
\[ \Lambda h = \alpha(h)\Lambda, \quad \lambda \rightarrow h = \lambda(h)g \quad \text{for all} \quad h \in H, \]

where $\lambda \in H^*$ is a non-zero right integral, and $\Lambda \in H$ is a non-zero left integral. These distinguished group-like elements are closely related to the antipode, as indicated by the following celebrated formula of Radford [26]:
\[ S^4(h) = g(\alpha \rightarrow h \leftarrow \alpha^{-1})g^{-1} \quad \text{for all} \quad h \in H. \] (1.2)

In particular, we find
\[ \text{ord}(S^2) \mid 2 \cdot \text{lcm}(\text{ord}(g), \text{ord}(\alpha)). \] (1.3)

The square of the antipode indeed determines the semisimplicity of a Hopf algebra. The following result, which will be used tacitly in the remaining discussion, was mainly proved by Larson and Radford [10, 11] (see also [16] for an alternative treatment of the result by Montgomery).

**Theorem 1.1.** The following statements on a finite-dimensional Hopf algebra $H$ over an algebraically closed field of characteristic zero with antipode $S$ are equivalent:

(a) $H$ is semisimple;
(b) $H^*$ is semisimple;
(c) $\text{Tr}(S^2) \neq 0$;
(d) $S^2 = \text{id}_H$.

Let $a \in H$ be a group-like element of order $m$. Then $k[a]$ is a commutative Hopf subalgebra of $H$. Let $\omega \in k$ be a primitive $m$th root of unity and define
\[ e_{a,j} = \frac{1}{m} \sum_{i \in \mathbb{Z}_m} \omega^{-ij}a^i \quad \text{for} \quad j \in \mathbb{Z}_m. \] (1.4)
Then \( \{e_{a,j}\}_{j \in \mathbb{Z}_m} \) is a complete set of primitive idempotents of \( k[a] \), that is,
\[
e_{a,i} \cdot e_{a,j} = \delta_{ij} e_{a,i}, \quad \sum_{j \in \mathbb{Z}_m} e_{a,j} = 1.
\]

Therefore, for any right \( k[a] \)-module \( V \), we always have the \( k[a] \)-module decomposition
\[
V = \bigoplus_{i \in \mathbb{Z}_m} Ve_{a,i}.
\]
Note that \( k[a] = \bigoplus_{j \in \mathbb{Z}_m} ke_{a,j} \) as ideals of \( k[a] \). If \( V \) is a free right \( k[a] \)-module, then \( \text{ord}(a) \) divides \( \dim V \) and
\[
\dim Ve_{a,j} = \frac{\dim V}{\text{ord}(a)}.
\]

Obviously, the same conclusion can be drawn for left \( k[a] \)-modules \( V \). Moreover, one can construct the complete set of primitive idempotents \( \{e_{\beta,j}\} \) for each group-like element \( \beta \in H^* \) in the same way.

**Lemma 1.2.** Let \( H \) be a finite-dimensional Hopf algebra over \( k \) with antipode \( S \). Suppose that \( a \in G(H) \) and \( \beta \in G(H^*) \) are such that \( \beta(a) = 1 \), and write \( H_{ij} \) for \( He_{a,i} \leftarrow e_{\beta,j} \) for \( i \in \mathbb{Z}_{\text{ord}(a)} \) and \( j \in \mathbb{Z}_{\text{ord}(\beta)} \). Then the following hold.

(a) We have the \( k \)-linear space decomposition \( H = \bigoplus_{i,j} H_{ij} \), and
\[
\dim H_{ij} = \frac{\dim H}{\text{ord}(a) \cdot \text{ord}(\beta)} \quad \text{for all } i, j.
\]

(b) If \( H \) is not semisimple, then \( \text{Tr}(S^2|_{H_{ij}}) = 0 \) for all \( i, j \).

**Proof.** (a) By the Nichols–Zoeller theorem (see [24]), \( H \) is a free right \( k[a] \)-module. It follows, by the preceding remark, that \( \dim He_{a,i} = \dim H/\text{ord}(a) \) for \( i \in \mathbb{Z}_{\text{ord}(a)} \), and
\[
H = \bigoplus_{i \in \mathbb{Z}_{\text{ord}(a)}} He_{a,i}.
\]
Since \( \beta(a) = 1 \), it follows that
\[
(ha^i \leftarrow \beta = (h \leftarrow \beta)a^i \quad \text{for all integers } i \text{ and } h \in H.
\]
Let \( e = e_{a,i} \) for some \( i \in \mathbb{Z}_{\text{ord}(a)} \). Then \( (he) \leftarrow \beta = (h \leftarrow \beta)e \) for \( h \in H \). In particular, \( He \) is a right \( k[\beta] \)-module under the action \( \leftarrow \). Consider the left \( k[\beta] \)-module action on \( He \) defined by
\[
\beta \rightarrow x = x \leftarrow (\beta^{-1}) \quad \text{for all } x \in He.
\]
Since \( He \) is a left \( H \)-module, it admits a natural right \( H^* \)-comodule structure \( \rho : He \to He \otimes H^* \) with \( \rho(x) = \sum x^{(0)} \otimes x^{(1)} \) defined by \( hx = \sum x^{(0)} x^{(1)}(h) \) for all \( h \in H \). It is straightforward to check that \( \rho(\beta \rightarrow x) = \beta \cdot \rho(x) \) for \( x \in He \). Hence, \( He \) is a Hopf module in \( k[\beta] \mathcal{M}^{H^*} \). By the Nichols–Zoeller theorem, we find that \( He \) is a free left \( k[\beta] \)-module under the action \( \rightarrow \). By the preceding remark again, we have
\[
He = \bigoplus_{j} e_{\beta,j} \rightarrow He \quad \text{and} \quad \dim (e_{\beta,j} \rightarrow He) = \frac{\dim He}{\text{ord}(\beta)} = \frac{\dim H}{\text{ord}(a) \cdot \text{ord}(\beta)}.
\]
Since \( e_{\beta,j} \rightarrow x = x \leftarrow e_{\beta,-j} \), we obtain
\[
He = \bigoplus_{j} H_{ij} \quad \text{and} \quad \dim H_{ij} = \frac{\dim H}{\text{ord}(a) \cdot \text{ord}(\beta)}.
\]
(b) Let \( E_i \) and \( F_j \) denote the \( k \)-linear operators on \( H \) defined by
\[
E_i(h) = he_{a,i}, \quad F_j(h) = h \leftarrow e_{\beta,j} \quad \text{for} \quad i \in \mathbb{Z}_{\text{ord}(a)}, \ j \in \mathbb{Z}_{\text{ord}(\beta)}.
\]
Then both \( E_i \) and \( F_j \) are projections on \( H \) and \( H_{ij} = F_j E_i(H) \). Since \( S^2(a) = a \) and \( \beta \circ S^2 = \beta \), the operator \( S^2 \) commutes with both \( E_i \) and \( F_j \). Therefore, \( S^2(H_{ij}) \subseteq H_{ij} \), and so
\[
\text{Tr}(S^2|_{H_{ij}}) = \text{Tr}(S^2 \circ F_j \circ E_i) = \text{Tr}(E_i \circ S^2 \circ F_j).
\]
It follows, by [28, Proposition 2(a)], that
\[
\text{Tr}(S^2|_{H_{ij}}) = \lambda(e_{a,i})e_{\beta,j}(\Lambda) = \sum_{i,k} \gamma_{ik} \lambda(a_i^1) \beta^k(\Lambda) \quad (1.5)
\]
for some \( \gamma_{ik} \in k \), where \( \lambda \in H^* \) is a right integral, and \( \Lambda \in H \) is a left integral such that \( \lambda(\Lambda) = 1 \). The properties of integrals imply the equalities
\[
\lambda(a_i^1) a^l = \lambda(a_i^1) 1, \quad \beta^k(\Lambda) \beta^l = \beta^k(\Lambda) \varepsilon \quad (1.6)
\]
for all integers \( l \) and \( k \). Since \( H \) is not semisimple, it follows that \( \lambda(1_H) = \varepsilon(\Lambda) = 0 \). If \( a_i^1 \) is not trivial, then the first equality of (1.6) and the linear independence of distinct group-like elements imply that \( \lambda(a_i^1) = 0 \). Similarly, we can also conclude that \( \beta^k(\Lambda) = 0 \) for all integers \( k \). In view of (1.5), \( \text{Tr}(S^2|_{H_{ij}}) = 0 \) for all \( i \) and \( j \). \( \square \)

Recall that a Hopf subalgebra \( A \) of a finite-dimensional Hopf algebra \( H \) is normal if and only if \( \sum_{(h)} h_1 a S(h_2), \sum_{(h)} S(h_1) a h_2 \in A \) for all \( h \in H \) and \( a \in A \). Since \( H \) is finite-dimensional, it follows that \( A \) is a normal Hopf subalgebra of \( H \) if and only if \( A^+ H = H A^+ \), which is in turn equivalent to \( A^+ H \subseteq H A^+ \) or \( H A^+ \subseteq A^+ H \), where \( A^+ = A \cap \ker \varepsilon \) (see [15, Section 3.4] or [19, Corollary 16], for example).

Following [30], we say that a sequence of finite-dimensional Hopf algebras
\[
1 \longrightarrow A \overset{i}{\longrightarrow} H \overset{\pi}{\longrightarrow} B \longrightarrow 1 \quad (1.7)
\]
is exact if \( i \) and \( \pi \) are injective and surjective Hopf algebra maps, respectively, such that \( \varepsilon(A) \) is normal in \( H \) and \( \ker \pi = H \varepsilon(A^+) \). In this case, \( H \) is called an extension of \( B \) by \( A \). Moreover, the dual sequence
\[
1 \longrightarrow B^* \overset{\pi^*}{\longrightarrow} H^* \overset{\varepsilon^*}{\longrightarrow} A^* \longrightarrow 1 \quad (1.8)
\]
of (1.7) is also an exact sequence of Hopf algebras.

The next sequence of propositions on some extensions of finite-dimensional Hopf algebras will be used to show the main theorem in the next two sections, and may be of interest in their own right.

**Proposition 1.3.** Let \( H \) and \( A \) be finite-dimensional Hopf algebras over \( k \) of dimension \( 2n \) and \( n \), respectively, where \( n \) is an odd integer. Then the following hold.

(a) If there exists a Hopf algebra surjection \( \pi : H \rightarrow A \), then
\[
R = H^{co \pi} = \{ h \in H \mid (id_H \otimes \pi) \Delta(H) = h \otimes 1_A \}
\]
is a normal Hopf subalgebra of \( H \) that is isomorphic to \( k[\mathbb{Z}_2] \).

(b) If \( A \) is a Hopf subalgebra of \( H \), then \( A \) is a normal Hopf subalgebra of \( H \).

**Proof.** (a) It is well known that \( R \) is a left coideal subalgebra of \( H \) of dimension 2, and \( HR^+ \subseteq R^+ H \). In view of the preceding remark, it suffices to show that \( R \) contains a non-trivial group-like element. Let \( x \) be a non-zero element of \( R \) such that \( \varepsilon(x) = 0 \). Then \( \{1, x\} \) is a basis for \( R \) and \( \Delta(x) = a \otimes 1 + b \otimes x \) for some \( a, b \in H \). By applying \( id_H \otimes \varepsilon \) and \( \varepsilon \otimes id_H \) to \( \Delta(x) \),
we find that \(a = x\) and \(\epsilon(b) = 1\). Noting that \((\text{id}_H \otimes \Delta)\Delta(x) = (\Delta \otimes \text{id}_H)\Delta(x)\), we obtain that \(b\) is a group-like element of \(H\), and so \(x\) is a \((1, b)\)-skew primitive element. Since \(H\) is finite-dimensional and \(x \neq 0\), we have \(b \neq 1\). Note that \(\{x\}\) is a basis for \(\ker \epsilon\|_R\), and \(bxb^{-1} \in R\). Since \(\epsilon(bxb^{-1}) = 0\), it follows that \(bxb^{-1} = \zeta x\) for some primitive \(M\)th root of unity \(\zeta \in \mathbb{k}\), where \(M \mid \text{ord}(b)\).

Suppose that \(x\) is a non-trivial \((1, b)\)-skew primitive element. Then, by [1, Proposition 1.8], \(\zeta \neq 1\) and \(x\) and \(b\) generate a Hopf subalgebra \(K \cong K_\mu(\text{ord}(b), \zeta)\) for some \(\mu \in \{0, 1\}\). In particular, we have

\[
M^2 \mid \dim K \mid \dim H.
\]

On the other hand, since \(\epsilon(x^2) = 0\), it follows that \(x^2 = \gamma x\) for some \(\gamma \in \mathbb{k}\). Therefore, \((bxb^{-1})^2 = \gamma x\), which implies that \(\gamma \zeta^2 = \gamma \zeta\). Thus \(\gamma = 0\), and hence \(x^2 = 0\). As a consequence, \(K \cong K_0(\text{ord}(b), \zeta)\) and \(M = 2\) is the nilpotency index of \(x\). In particular, \(4 \mid \dim H\), which is a contradiction. Therefore, \(x\) must be a trivial \((1, b)\)-skew primitive element, and hence \(x = \nu(1 - b)\) for some non-zero \(\nu \in \mathbb{k}\). This implies that \(b \in R\), and so \(R = k[b]\).

(b) Consider the dual of the inclusion map \(A \hookrightarrow H\), which is a Hopf algebra surjection \(\pi : H^* \to A^*\). By part (a), \((H^*)^{co \pi} \cong k[\mathbb{Z}_2]\) is a normal Hopf subalgebra of \(H^*\), and so we have the following exact sequence of Hopf algebras:

\[
1 \to k[\mathbb{Z}_2] \to H^* \xrightarrow{\pi} A^* \to 1.
\]

Dualizing this exact sequence, the result follows. \(\square\)

**Remark 1.4.** Susan Montgomery has pointed out that Proposition 1.3(b) is a generalization of Proposition 2 in [9] to non-semisimple Hopf algebras of dimension \(2n\) with \(n\) odd.

The following result generalizes Lemma 5.1 in [20]. This proposition and its corollary provide a useful way of eliminating certain cases in the next section, especially since we are dealing with non-semisimple Hopf algebras.

**Proposition 1.5.** Let \(H\) be a finite-dimensional Hopf algebra over \(\mathbb{k}\). If there exist semisimple Hopf subalgebras \(A \subset H\) and \(K \subset H^*\) such that \(\dim H = (\dim A) (\dim K)\) and \(\gcd(\dim A, \dim K) = 1\), then \(H\) is semisimple.

**Proof.** Define the Hopf algebra surjection

\[
\pi : H \cong H^{co \pi} \xrightarrow{i^*} K^*,
\]

where \(i : K \to H^*\) is inclusion. As \(\gcd(\dim A, \dim K) = 1\), it follows that the image of \(A\) under \(\pi\) is one-dimensional. Moreover, \(A^+ \subseteq \ker \pi\), and so

\[
\pi(a) = \pi(a - \epsilon(a) 1) + \pi(\epsilon(a) 1) = \epsilon(a) \pi(1)
\]

for all \(a \in A\). Therefore, \(A \subseteq H^{co \pi} = \{ h \in H \mid h_1 \otimes \pi(h_2) = h \otimes 1_K \}\). However, \(\dim H^{co \pi} = \dim H / \dim K = \dim A\), and so \(A = H^{co \pi}\). It follows, by [29], that \(H\) is isomorphic to a cross product algebra \(A \#_\sigma K^*\) for some 2-cocycle \(\sigma\). By [3, Theorem 2.6], the semisimplicity of \(A\) and \(K^*\) implies the semisimplicity of \(H\). \(\square\)

**Corollary 1.6.** Suppose that \(n\) is an odd integer. If \(H\) is a \(2n\)-dimensional Hopf algebra over the field \(\mathbb{k}\), and \(H\) contains a semisimple Hopf subalgebra of dimension \(n\), then \(H\) is semisimple.
Proof. Let $K$ be a semisimple Hopf subalgebra of $H$ with $\dim K = n$. Then there is a Hopf algebra surjection $\pi : H^* \rightarrow K^*$ and $K^*$ is semisimple. By Proposition 1.3, we have the exact sequence of Hopf algebras as follows:

$$1 \rightarrow k[\mathbb{Z}_2] \rightarrow H^* \xrightarrow{\pi} K^* \rightarrow 1.$$ 

By Proposition 1.5, $H$ is semisimple.

The Taft algebras have been the basic examples of non-semisimple Hopf algebras (see [33]). The next proposition implies the existence of some semisimple Hopf subalgebras in the dual of an extension of a finite group algebra by a Taft algebra. We will need this result in the proof of Lemma 3.4 in the last section.

**Proposition 1.7.** Let $H$ be a finite-dimensional Hopf algebra over $k$ and let $A$ be a normal Hopf subalgebra of $H$ such that $H/HA^+$ is isomorphic to $k[G]$ for some finite group $G$. If the Jacobson radical $J$ of $A$ is a Hopf ideal of $A$, then $HJ$ is a Hopf ideal of $H$, and we have the exact sequence of Hopf algebras as follows:

$$1 \rightarrow A/J \rightarrow H/HJ \rightarrow k[G] \rightarrow 1.$$ 

In particular, $H^*$ admits a semisimple Hopf subalgebra of dimension $|G| \dim(A/J)$.

Proof. Since $H/HA^+ \cong k[G]$ as Hopf algebras, by [29], the (right) $k[G]$-extension $A \subset H$ is $H$-cleft. Therefore, there exists a convolution invertible right $k[G]$-comodule map $\gamma : k[G] \rightarrow H$ with the convolution inverse $\gamma'$ such that $\gamma(1) = 1_H$, and $\gamma(g)A\gamma'(g) \subseteq A$ for all $g \in G$, and $\sigma(g,h) = \gamma(g)\gamma(h)\gamma'(gh)$ for $g,h \in G$ defines a 2-cocycle on $G$ with coefficients in $A$. Moreover, the $k$-linear map $\Phi : A\#_s k[G] \rightarrow H$ defined by $a\# g \mapsto a\gamma(g)$ is an algebra isomorphism (cf. [15]). In particular, $H = \bigoplus_{g \in G} A\gamma(g)$ as $k$-linear spaces.

Note that $\gamma(g)$ is an invertible element of $H$ with inverse $\gamma'(g)$ for all $g \in G$, since $\gamma \ast \gamma'(g) = 1_H$. Therefore, $a \mapsto \gamma(g)a\gamma'(g)$ defines an algebra automorphism on $A$. In particular, we find that $J = \gamma(g)J\gamma'(g)$. Thus, we have

$$\gamma(g)A = A\gamma(g), \quad \gamma(g)J = J\gamma(g) \quad \text{for all } g \in G.$$ 

Therefore, we have

$$JH = \sum_{g \in G} JA\gamma(g) = \sum_{g \in G} J\gamma(g) = \sum_{g \in G} \gamma(g)J = \sum_{g \in G} \gamma(g)AJ = HJ,$$

and hence $HJ$ is a nilpotent Hopf ideal of $H$.

If $a \in A \cap HJ$, then $Aa \subseteq HJ$ is also nilpotent, and so $a \in J$. Therefore, the natural map $\iota : A/J \rightarrow H/HJ$ induced from the inclusion map $i : A \rightarrow H$ is also injective. Since $A$ is normal in $H$, it follows that $\iota(A/J)$ is normal in $H/HJ$. Let $\pi : H/HJ \rightarrow H/HA^+ = J^\perp$ be the natural surjection. It is immediate to see that $\ker \pi = HA^+/HJ = (H/HJ)i(A/J)^+$. Therefore, the sequence of finite-dimensional Hopf algebras

$$1 \rightarrow A/J \xrightarrow{i} H/HJ \xrightarrow{\pi} H/HA^+ \rightarrow 1$$

is exact. Consequently, $H/HJ$ is a crossed product $A/J\#_s k[G]$, and hence semisimple by [3, Theorem 2.6]. Moreover, $\dim H/HJ = |G| \dim(A/J)$. Since $(H/HJ)^*$ is isomorphic to a Hopf subalgebra of $H^*$, the second statement follows.

We close this section with a few results on linear algebra that will be used frequently together with Lemma 1.2 to determine the order of an antipode in the next section. The first two results are known, and we prove the third.
**Lemma 1.8.** Let $V$ be a finite-dimensional vector space over the field $k$, let $p$ be a prime, and let $T$ be a linear automorphism on $V$ such that $\text{Tr}(T) = 0$. Then the following hold.

(a) If $T^{2p} = \text{id}_V$, then $\text{Tr}(T^p) = pd$ for some integer $d$ (see [2, Lemma 2.6]).
(b) If $T^n = \text{id}_V$ for some positive integer $n$, then $p$ divides the dimension of $V$ (see [22, Lemma 1.4]).
(c) If $\dim V = p$ and $T^m = \text{id}_V$ for some positive integer $m = 2^n p$, where $p$ is odd, then $T^p = \xi \text{id}_V$ for some $2^n$th root of unity $\xi \in k$.

**Proof.** We prove part (c). The statement is obviously true for $n = 0$. We assume that $n \geq 1$. Let $\omega \in k$ be a primitive $m$th root of unity and let $V_b$ be the eigenspace of $T$ associated to the eigenvalue $\omega^b$. We consider the polynomial $f(x) = \sum_{b=0}^{m-1} (\dim V_b)\omega^b = f(\omega)$, we have $f(x) = g(x)\Phi_m(x)$ for some $g(x) \in \mathbb{Z}[x]$, where $\Phi_k$ denotes the $k$th cyclotomic polynomial. Therefore, we have

$$0 = \text{Tr}(T) = \sum_{b=0}^{m-1} (\dim V_b)\omega^b = f(\omega),$$

we have $f(x) = g(x)\Phi_m(x)$ for some $g(x) \in \mathbb{Z}[x]$, where $\Phi_k$ denotes the $k$th cyclotomic polynomial. Therefore, we have

$$\text{Tr}(T^p) = f(\omega^p) = g(\omega^p)\Phi_m(\omega^p).$$

(1.9)

Note that $\{\omega^{pi} | i = 0, \ldots, 2^{n-1} - 1\}$ is a basis for $\mathbb{Q}(\omega^p)$ and $\Phi_m(x) = \Phi_p(-x^{2^{n-1}})$. Therefore, we have

$$\Phi_m(\omega^p) = \Phi_p(-\omega^p)^{2^{n-1}} = \Phi_p(1) = p.$$  

(1.10)

Let $W_i$ be the eigenspace of $T^p$ associated to the eigenvalue $\omega^{pi}$. Since

$$\omega^{pi(1+2^{n-1})} = -\omega^{pi} \quad \text{for} \quad i = 0, \ldots, 2^{n-1} - 1,$$

we have

$$\text{Tr}(T^p) = \sum_{i=0}^{2^{n-1}-1} (\dim W_i - \dim W_{2^{n-1}+i})\omega^{pi}.$$  

There exists $i$ such that $\dim W_i - \dim W_{2^{n-1}+i} \neq 0$, otherwise $\dim V$ is even. By equations (1.9) and (1.10), $p | \dim W_i - \dim W_{2^{n-1}+i}$. Since $\dim V = p$, only one of the eigenspaces $W_i$ and $W_{2^{n-1}+i}$ is non-zero and any other eigenspace of $T^p$ is trivial. Thus, $T^p = \xi \text{id}_V$ for some $2^n$th root of unity $\xi \in k$. \hfill \Box

2. The order of the antipode

Throughout the remainder of this paper, we assume that $H$ is a non-semisimple Hopf algebra of dimension $2p^2$ over $k$ with antipode $S$, where $p$ is an odd prime. We will prove in this section that the antipodes of these Hopf algebras are of order $2p$ (Theorem 2.5).

To establish this result, we first consider the distinguished group-like elements $g \in H$ and $\alpha \in H^*$. Since $4 | \dim H = 2p^2$, it follows, by [22, Corollary 2.2], that one of the distinguished group-like elements $g$ or $\alpha$ is non-trivial. In view of the Nichols–Zoeller theorem, we have

$$\text{lcm}(\text{ord}(g), \text{ord}(\alpha)) = 2, 2p, 2p^2, \text{ or } 2p^2.$$  

Without loss of generality, we may assume that

$$\text{ord}(g) \geq \text{ord}(\alpha)$$  

(2.1)

by duality. Under this assumption, $\text{ord}(g) > 1$.

We write $e_i$ for the idempotent $e_{g,i} \in k[g]$ defined in (1.4), and $f_j$ for $e_{\alpha,j} \in k[\alpha]$. We define

$$H_{ij} = He_i \leftarrow f_j \quad \text{for all} \quad i \in \mathbb{Z}_{\text{ord}(g)} \text{ and } j \in \mathbb{Z}_{\text{ord}(\alpha)}.$$  

(2.2)
It follows, by Lemma 1.2, that
\[
\dim H e_i = \frac{\dim H}{\operatorname{ord}(g)} \quad \text{and} \quad \operatorname{Tr}(S^2|_{H e_i}) = 0
\]
for all \( i \in \mathbb{Z}_{\operatorname{ord}(g)} \). If \( \alpha(g) = 1 \), then we also have
\[
\operatorname{Tr}(S^2|_{H e_i}) = 0 \quad \text{for all } i, j.
\]
We first eliminate those values of \( \operatorname{lcm}(\operatorname{ord}(g), \operatorname{ord}(\alpha)) \) that are not possible.

**Lemma 2.1.** The only possible values of \( \operatorname{lcm}(\operatorname{ord}(g), \operatorname{ord}(\alpha)) \) are \( p \) and \( 2p \).

**Proof.** Assume that either \( \operatorname{lcm}(\operatorname{ord}(g), \operatorname{ord}(\alpha)) = 2p^2 \) or \( p^2 \). Since \( \operatorname{ord}(g) \geq \operatorname{ord}(\alpha) \), it follows that \( \operatorname{ord}(g) = p^2 \) in both cases. Thus \( g \) generates a \( p^2 \)-dimensional semisimple Hopf subalgebra of \( H \). By Corollary 1.6, \( H \) must be semisimple, which is a contradiction.

If \( \operatorname{lcm}(\operatorname{ord}(g), \operatorname{ord}(\alpha)) = 2 \), then \( \operatorname{ord}(g) = 2 \) and \( \operatorname{ord}(\alpha) = 1 \) or \( 2 \). By Lemma 1.2, \( \dim H e_i = p^2 \) and \( \operatorname{Tr}(S^2|_{H e_i}) = 0 \) for \( i \in \mathbb{Z}_2 \). Using Radford’s formula (1.2), we have that \( S^8 = \text{id}_H \). In particular, \( (S^2|_{H e_i})^4 = \text{id}_{H e_i} \). It follows, by Lemma 1.8(b), that \( 2 | \dim H e_i = p^2 \), which is another contradiction.

Note that if \( \operatorname{lcm}(\operatorname{ord}(g), \operatorname{ord}(\alpha)) = p \) or \( 2p \), then \( \operatorname{ord}(g) = p \) or \( 2p \) as we are assuming that \( \operatorname{ord}(g) \geq \operatorname{ord}(\alpha) \). We first eliminate the possibility that \( \operatorname{ord}(g) = p \) and \( \operatorname{ord}(\alpha) = 2 \).

**Lemma 2.2.** The pair \( (\operatorname{ord}(g), \operatorname{ord}(\alpha)) \) cannot be \( (p, 2) \).

**Proof.** Suppose that \( \operatorname{ord}(g) = p \) and \( \operatorname{ord}(\alpha) = 2 \). Then, by Radford’s formula (1.2), \( S^{8p} = \text{id}_H \). Since \( p \) is an odd prime, we find that \( \alpha(g) = 1 \). From Lemma 1.2, we get
\[
\dim H_{ij} = \frac{\dim H}{\operatorname{ord}(g) \cdot \operatorname{ord}(\alpha)} = p, \quad \operatorname{Tr}(S^2|_{H e_i}) = 0
\]
for all \( i \in \mathbb{Z}_p \) and \( j \in \mathbb{Z}_2 \), and \( H \) is a direct sum of the subspaces \( H_{ij} \) defined in (2.2). By Lemma 1.8(c), it follows that \( (S^2|_{H_{ij}})^p = \zeta_{ij} \text{id}_{H_{ij}} \) for some fourth root of unity \( \zeta_{ij} \in \mathbb{K} \). Since \( e_i \leftarrow f_0 = e_i \), and \( S^2(e_i) = e_i \), it follows that \( \zeta_{i0} = 1 \) for all \( i \in \mathbb{Z}_p \). Let \( V_j = \bigoplus_i H e_i \leftarrow f_j = H \leftarrow f_j \) for \( j \in \mathbb{Z}_2 \). Then \( S^{2p}|_{V_0} = \text{id}_{V_0} \). Thus, for \( x \in V_0 \), we have
\[
x = S^{2p}(x) = \alpha \rightarrow x \leftarrow \alpha = \alpha \rightarrow x.
\]
Let \( L(\alpha) \) denote the linear operator on \( H \) defined by \( L(\alpha)(x) = \alpha \rightarrow x \). Then \( L(\alpha)^2 = \text{id}_H \), \( \operatorname{Tr}(L(\alpha)) = 0 \), and \( \operatorname{Tr}(L(\alpha)|_{V_0}) = p^2 \). Since \( L(\alpha)(V_1) \subseteq V_1 \), it follows that \( L(\alpha)|_{V_1} = -\text{id}_{V_1} \).

Therefore, \( \alpha \rightarrow x \leftarrow \alpha = x \) for all \( x \in V_1 \), and hence \( S^{2p} = \text{id}_H \). In particular, \( H \) is of index \( p \).

It follows, by [21, Corollary 3.2], that the subspace
\[
H_- = \{ x \in H \mid S^{2p}(x) = -x \}
\]
is of even dimension. Since \( S^{2p}|_{V_0} = \text{id}_{V_0} \), it follows that \( H_- \subseteq V_1 \).

Let \( V_{j+} \) and \( V_{j-} \) denote the eigenspaces of \( S^2|_{V_j} \) associated to the eigenvalues \( 1 \) and \( -1 \), respectively. Since the \( p \) distinct eigenvalues of \( S^2|_{H_{i1}} \) are \( \zeta_{i1}, \zeta_{i1} \omega, \ldots, \zeta_{i1} \omega^{p-1} \), where \( \omega \in \mathbb{K} \) is a primitive \( p \)-th root of unity, we find that
\[
\dim \{ x \in V_1 \mid S^{2p}(x) = x \} = p \dim V_{1+}, \quad \dim H_- = p \dim V_{1-}.
\]
Let \( \lambda \in H^* \) be a non-zero right integral. We claim that \( (x, y) = \lambda(xy) \) defines a non-degenerate alternating form on \( V_{1+} \). It follows, by [28], that
\[
(x, y) = \lambda(xy) = \lambda(S^2(y \leftarrow \alpha)x) = -\lambda(yx) = -(y, x)
\]
for all $x, y \in V_{1+}$. Moreover, we have

$$\lambda(S^2(v)) = \alpha(g)\lambda(v) = \lambda(v) = \lambda(\alpha \cdot v) \quad \text{for all } v \in H.$$  

Therefore, $\lambda(v) = 0$ for any $v \in H$ that satisfies $S^2(v) = \mu v$ or $\alpha \cdot v = \mu v$ for some $\mu \in \mathbb{k}$ not equal to $1$. Let $x \in V_{1+}$ be such that $\lambda(xy) = 0$ for all $y \in V_{1+}$. Then $\lambda(xy') = 0$ for all $y' \in H$. By the non-degeneracy of $\lambda$ on $H$, we have $x = 0$, and hence $(\cdot, \cdot)$ is non-degenerate on $V_{1+}$. Thus, $\dim V_{1+}$ is even. Note that $p \dim V_{1+} + \dim H_- = \dim V_1 = p^3$. This implies that $p^2$ is even, which is a contradiction. \hfill \square

We now proceed to show that $S^{2p} = \text{id}_H$ for the remaining possibilities of $\text{lcm}(\text{ord}(g), \text{ord}(\alpha))$. We shall use this to deduce in the next section that $H$ or $H^*$ is pointed.

**Lemma 2.3.** If $\text{lcm}(\text{ord}(g), \text{ord}(\alpha)) = 2p$, then $S^{2p} = \text{id}_H$.

**Proof.** Under this hypothesis, $S^{2p} = \text{id}_H$ by Radford’s formula (1.2). Moreover, either $\text{ord}(g) = 2p$ or $(\text{ord}(g), \text{ord}(\alpha)) = (p, 2)$. The second case can be eliminated by Lemma 2.2. Therefore, $\text{ord}(g) = 2p$, and $\dim H_\epsilon = p$ for $i \in \mathbb{Z}_{2p}$. Fix $i \in \mathbb{Z}_{2p}$ and set $T_i = S^2|H_\epsilon$. Then $T_i^* = \text{id}_{H_\epsilon}$ and $\text{Tr}(T_i) = 0$. By Lemma 1.8(c), we have $T_i^p = \zeta_i \text{id}_{H_\epsilon}$, where $\zeta_i \in \mathbb{k}$ is a fourth root of unity. Note that

$$T_i(e_i) = S^2(e_i) = e_i.$$  

Therefore, $\zeta_i = 1$, and so $T_i^p = \text{id}_{H_\epsilon}$ for all $i \in \mathbb{Z}_{2p}$. Hence, we get that $S^{2p} = \text{id}_H$, as desired. \hfill \square

We now deal with the remaining case in the following lemma.

**Lemma 2.4.** If $\text{lcm}(\text{ord}(g), \text{ord}(\alpha)) = p$, then $S^{2p} = \text{id}_H$.

**Proof.** The proof will be presented in steps (i)–(v).

(i) Since $\text{lcm}(\text{ord}(g), \text{ord}(\alpha)) = p$, it follows that $S^{4p} = \text{id}_H$ by Radford’s formula (1.2). In particular, the possible eigenvalues of $S^{2p}$ are $\pm 1$. Define

$$H_+ = \{ x \in H \mid S^{2p}(x) = x \}, \quad H_- = \{ x \in H \mid S^{2p}(x) = -x \}.$$  

Then we have

$$\dim H_+ + \dim H_- = 2p^2 \quad \text{and} \quad \text{Tr}(S^{2p}) = \dim H_+ - \dim H_- \quad (2.3)$$

(ii) The pair $(\text{ord}(g), \text{ord}(\alpha))$ can either be $(p, 1)$ or $(p, p)$. In both cases, $\text{ord}(g) = p$. Hence $\text{lcm}(\text{ord}(g), \text{ord}(S^4)) = p$, or, equivalently, $H$ is of index $p$. It follows, by [21, Proposition 1.3], that $\dim H_-$ is an even integer.

(iii) If $(\text{ord}(g), \text{ord}(\alpha)) = (p, p)$, then $\alpha(g) \neq 1$. Otherwise, we can apply Lemma 1.2 and get

$$\dim H_{ij} = 2, \quad \text{Tr}(S^2|_{H_{ij}}) = 0, \quad \text{and} \quad H = \bigoplus_{i,j \in \mathbb{Z}_p} H_{ij},$$

where $H_{ij}$ are defined in (2.2). By (i), we find that $(S^2|_{H_{ij}})^{2p} = \text{id}_{H_{ij}}$, and so $S^{2p}|_{H_{ij}}$ has exactly two distinct eigenvalues $\pm \xi$ for some $p$th root of unity $\xi \in \mathbb{k}$. Therefore, $\pm 1$ are the two distinct eigenvalues of $S^{2p}|_{H_{ij}}$. This implies that $\dim H_- = \dim H_+ = p^2$, which contradicts (ii).

(iv) We claim that $\text{Tr}(S^{2p}) = p^2d$ for some integer $d$. If $(\text{ord}(g), \text{ord}(\alpha)) = (p, 1)$, then $H$ is a unimodular Hopf algebra of index $p$ by (ii). It follows immediately, by [20, Lemma 4.3], that $\text{Tr}(S^{2p}) = p^2d$ for some integer $d$. We may now assume that $(\text{ord}(g), \text{ord}(\alpha)) = (p, p)$. Let
\[ B = k[g] \text{ and } I = k[\alpha]^{\perp}, \text{ which is a Hopf ideal of } H, \text{ and } \overline{H} = H/I \cong k[\alpha]^* \cong B. \text{ Let } \pi : H \to B \text{ be such a surjection of Hopf algebras. By (iii), } \alpha(g) \neq 1, \text{ and so } g - 1 \not\in k[\alpha]^{\perp}, \text{ or, equivalently, } \pi(g) \neq 1_\overline{\pi}. \text{ Since } \dim \overline{H} = p, \text{ it follows that } \pi(B) = \overline{H}. \text{ Therefore, the composition } \pi \circ i : B \to \overline{H} \text{ is an isomorphism of Hopf algebras, where } i : B \to H \text{ is inclusion. Thus, there exists a surjective Hopf algebra map } \nu : H \to B \text{ such that } \nu \circ i = \text{id}_B. \text{ Hence, by } [27], H \text{ is isomorphic to the biproduct } R \times B, \text{ where } R \text{ is the right coinvariant given by}
\[
R = H^{\text{co} \nu} = \{ h \in H \mid (\text{id}_H \otimes \nu)\Delta(h) = h \otimes 1_B \}.
\]
Due to the results in [2, Section 4], \( R \) is invariant under \( S^2 \) and \( S^2 = T \otimes S^2|_B \), where \( T = S^2|_R \) if one identifies \( H \) with \( R \times B \). Since \( S^2|_B = \text{id}_B \) and
\[
0 = \text{Tr}(S^2) = \text{Tr}(T)\text{Tr}(\text{id}_B) = \text{Tr}(T)p,
\]

it follows that \( \text{Tr}(T) = 0 \). Also, we have that \( T^{2p} = \text{id}_R \) as \( S^{2p} = \text{id}_H \). Thus, by Lemma 1.8(b), \( \text{Tr}(T^p) = pd \) for some integer \( d \). Therefore, we have
\[
\text{Tr}(S^{2p}) = \text{Tr}(T^p)\text{Tr}(\text{id}_B) = p^2d,
\]
as claimed.

(v) The equalities in (2.3) imply that \( d \) is an even integer. Since
\[
-2p^2 \leq \text{Tr}(S^{2p}) \leq 2p^2,
\]
it follows that \( d \) can only be \(-2, 0, \) or \( 2 \). Note that, if \( d = -2 \), then \( S^{2p} = -\text{id}_H \), which is not possible as \( S^{2p}(1_H) = 1_H \). If \( d = 0 \), then \( \text{Tr}(S^{2p}) = 0 \), and hence \( \dim H_+ = \dim H_- = p^2 \). However, this contradicts (ii) that asserts that \( \dim H_- \) is even. Hence \( d = 2 \), and so \( \text{Tr}(S^{2p}) = 2p^2 \), which implies that \( S^{2p} = \text{id}_H \), as desired.

\[\square\]

With the beginning remarks and these four lemmas, we have proved the following theorem.

**Theorem 2.5.** Let \( p \) be an odd prime and let \( H \) be a non-semisimple Hopf algebra over \( k \) of dimension \( 2p^2 \). Then the order of the antipode of \( H \) is \( 2p \).

3. **Non-semisimple Hopf algebras of dimension \( 2p^2 \)**

In this section, we will show that, if \( H \) is a non-semisimple Hopf algebra of dimension \( 2p^2 \) over \( k \) for an odd prime \( p \), then \( H \) or \( H^* \) is pointed. This completes the proof of our main result Theorem I. Recall that a Hopf algebra \( H \) over \( k \) is pointed if its simple subcoalgebras are all one-dimensional. Therefore, \( H^* \) is pointed if all simple \( H \)-modules are one-dimensional.

We continue to assume that \( H \) is a non-semisimple Hopf algebra of dimension \( 2p^2 \) over the field \( k \) with the antipode \( S \), where \( p \) is an odd prime. Again, we let \( g \in G(H) \) and \( \alpha \in G(H^*) \) denote the distinguished group-like elements. From Section 2, we know that the order of the antipode \( S \) of \( H \) is \( 2p \), and that
\[
\text{lcm}(\text{ord}(g), \text{ord}(\alpha)) = p \text{ or } 2p.
\]

By duality, we assume that \( \text{ord}(\alpha) \geq \text{ord}(g) \) in this section. Therefore, \( \text{ord}(\alpha) = p \text{ or } 2p \). Note that the opposite assumption was made in Section 2.

For any finite-dimensional \( H \)-module \( V \), the left dual \( V^* \) of \( V \) is the \( H \)-module with the underlying space \( V^* = \text{Hom}_k(V, k) \) and the \( H \)-action given by
\[
(h \cdot f)(v) = f(S(h)v) \quad \text{for all } f \in V^* \text{ and } v \in V.
\]

For an algebra automorphism \( \sigma \) on \( H \), let \( \sigma V \) be the \( H \)-module with the underlying space \( V \) and the action given by \( h \cdot \sigma v = \sigma(h)v \) for all \( h \in H \) and \( v \in V \). It is easy to verify that the
natural isomorphism \( j : V \to V^{**} \) of vector spaces is also an \( H \)-module map from \( S^2V \) to \( V^{\vee\vee} \). Hence, we have

\[
S^2V \cong V^{\vee\vee} \quad \text{for } V \in \text{H-mod}_{\text{fin}}. \tag{3.1}
\]

Let \( P(V) \) denote the projective cover of \( V \in \text{H-mod}_{\text{fin}} \). For \( \beta \in G(H^*) \), we define \( k_\beta \) as the one-dimensional \( H \)-module that affords the irreducible character \( \beta \). We simply denote by \( k \) the trivial one-dimensional \( H \)-module \( k_\epsilon \).

We denote by \([V]\) the isomorphism class of a simple \( H \)-module \( V \). The cyclic group \( G = \langle \alpha \rangle \) acts on the set \( \text{Irr}(H) \) of all isomorphism classes of simple \( H \)-modules by setting

\[
\beta[V] = [k_\beta \otimes V]
\]

for all \( \beta \in G \) and \([V] \in \text{Irr}(H) \). We denote the \( G \)-orbit of \([V]\) in \( \text{Irr}(H) \) by \( O(V) \). Since \( k_\beta \otimes - \) is a \( k \)-linear equivalence on \( \text{H-mod}_{\text{fin}} \), we have \( P(k_\beta \otimes V) \cong k_\beta \otimes P(V) \), and thus \( \dim P(W) = \dim P(V) \) for all \([W] \in O(V) \). In particular, \( \dim P(k) = \dim P(k_\beta) \) for all \( \beta \in G \). Suppose that \( \{[V_0], [V_1], \ldots, [V_t]\} \) is a complete set of representatives of \( G \)-orbits in \( \text{Irr}(H) \) with \( V_0 = k \). The left \( H \)-module \( H \) has the decomposition of principal modules as follows:

\[
H \cong \bigoplus_{[V] \in \text{Irr}(H)} (\dim V) \cdot P(V) 
\cong \bigoplus_{\beta \in \langle \alpha \rangle} k_\beta \otimes \bigoplus_{i=1}^t \dim V_i \left( \bigoplus_{[W] \in O(V_i)} P(W) \right). \tag{3.2}
\]

This decomposition implies the following equation:

\[
\dim H = \text{ord}(\alpha) \dim P(k) + \sum_{i>0} O(V_i) \dim V_i \cdot \dim P(V_i). \tag{3.3}
\]

We can now demonstrate that \( \dim P(k) \) can only take two possible values.

**Lemma 3.1.** The value of \( \dim P(k) \) can either be \( p \) or \( 2p \).

**Proof.** We have that

\[
P(k) \cong P(k^{\vee\vee}) \cong P(k)^{\vee\vee} \cong S^2P(k).
\]

Since \( S^{2p} = \text{id}_H \), by Lemma A.2 in the Appendix, there exists an \( H \)-module isomorphism

\[
\phi : P(k) \longrightarrow S^2P(k)
\]

such that \( \phi^p = \text{id}_{P(k)} \). It follows, by [23, Lemma 1.3], that \( \text{Tr}(\phi) = 0 \). In view of [2, Lemma 2.6] or Lemma 1.8(b), \( \dim P(k) = np \) for some positive integer \( n \), but then, by equation (3.3), we have

\[
2p^2 = \dim H \geq p \dim P(k) = np^2,
\]

and so \( n = 1 \) or \( 2 \).

In view of Lemma 3.1 and the beginning remark of this section, we find

\[
(\text{ord}(\alpha), \dim P(k)) = (2p, 2p), (p, 2p), (2p, p), \text{ or } (p, p). \tag{3.4}
\]

The following lemma settles the first three cases.

**Lemma 3.2.** The pair \((\text{ord}(\alpha), \dim P(k)) \neq (2p, 2p)\). If \((\text{ord}(\alpha), \dim P(k))\) is equal to either \((p, 2p)\) or \((2p, p)\), then \( H^* \) is pointed.
Proof. Let
\[ H_\alpha = \bigoplus_{\beta \in \kappa(\alpha)} P(\kappa_\beta). \]
Then \( H_\alpha \) is isomorphic to a left submodule of \( H \), and so \( \dim H_\alpha \leq \dim H = 2p^2 \). By the preceding remark, \( \dim H_\alpha = \text{ord}(\alpha) \dim P(\kappa) \). Therefore, it is not possible to have \( (\text{ord}(\alpha), \dim P(\kappa)) = (2p, 2p) \). If \( (\text{ord}(\alpha), \dim P(\kappa)) = (p, 2p) \) or \( (2p, p) \), then \( \dim H_\alpha = \dim H \), and hence \( H \cong H_\alpha \) as left \( H \)-modules. Since all of the simple quotients of \( H_\alpha \) are one-dimensional, every simple \( H \)-module is one-dimensional. Therefore, \( H^* \) is pointed.

Next we handle the remaining case that \( \text{ord}(\alpha) = \dim P(\kappa) = p \). Following the terminology in [5], an \( H \)-module \( V \) is called \( \alpha \)-stable if \( \kappa_\alpha \otimes V \cong V \). We have two subcases: either there exists an \( \alpha \)-stable simple \( H \)-module, or all simple \( H \)-modules are not \( \alpha \)-stable.

**Lemma 3.3.** If \( \text{ord}(\alpha) = \dim P(\kappa) = p \), and all of the simple \( H \)-modules are not \( \alpha \)-stable, then \( H^* \) is pointed.

Proof. Since \( \dim P(\kappa) = p = \text{ord}(\alpha) \), it follows, by (3.3), that there exists a simple \( H \)-module \( V \) such that \( [V] \notin O(\kappa) \). Since
\[ \text{Hom}_H(V^\vee \otimes P(V), \kappa) \cong \text{Hom}_H(P(V), V \otimes \kappa) \cong \text{Hom}_H(P(V), V) \]
and \( \dim \text{Hom}_H(P(V), V) = 1 \), we obtain \( \dim \text{Hom}_H(V^\vee \otimes P(V), \kappa) = 1 \). Thus, \( P(\kappa) \) is a direct summand of \( V^\vee \otimes P(V) \). In particular, we have
\[ \dim V \dim P(V) = \dim(V^\vee \otimes P(V)) \geq \dim P(\kappa) = p. \]
Since \( V \) is not \( \alpha \)-stable, it follows that \( |O(V)| = p \), and so (3.3) implies that
\[ 2p^2 = \dim H \geq p \dim P(\kappa) + p \dim V \dim P(V) \geq 2p^2. \]
Therefore, \( \dim V \dim P(V) = p \), which forces \( \dim V = 1 \) and \( \dim P(V) = p \). Thus all simple \( H \)-modules are one-dimensional, and so \( H^* \) is pointed.

**Lemma 3.4.** If \( \text{ord}(\alpha) = \dim P(\kappa) = p \), and there exists an \( \alpha \)-stable simple \( H \)-module, then \( H \) is pointed.

Proof. Assume that \( V \) is an \( \alpha \)-stable simple \( H \)-module. Then \( O(V) = \{ [V] \} \) and \( P(V) \) is also \( \alpha \)-stable. By [23, Lemma 1.4], both \( \dim V \) and \( \dim P(V) \) are multiples of \( p \). Let \( \dim V = np \) and \( \dim P(V) = mp \) for some positive integers \( n \leq m \). By (3.3), we have the inequality
\[ 2p^2 = \dim H \geq p \dim P(\kappa) + \dim V \dim P(V) \geq p^2 + nmp^2 = (nm + 1)p^2, \]
which implies that \( n = m = 1 \). Hence \( P(V) = V \) and \( \text{Irr}(H) = O(\kappa) \cup \{ [V] \} \) by (3.3). Recall from [23, Lemma 1.1] that the socle of \( P(\kappa) \) is \( \kappa_{\alpha - 1} \). Therefore,
\[ \text{Hom}_H(P(V), P(\kappa)) = \text{Hom}_H(V, P(\kappa)) = 0. \]
Since \( V \) is the only simple \( H \)-module of dimension greater than 1, all of the composition factors of \( P(\kappa) \) are one-dimensional. Now let \( \mathbf{E} \) be the full subcategory of all \( M \in \text{H-mod}_{\text{fin}} \) whose composition factors are one-dimensional. Thus \( \mathbf{E} \) is a proper tensor subcategory of \( \text{H-mod}_{\text{fin}} \), with \( P(\kappa) \in \mathbf{E} \), and all of the simple objects of \( \mathbf{E} \) are one-dimensional. There is a Hopf ideal \( I \) of \( H \) such that \( \mathbf{E} \) is equivalent to \( \text{H/I-mod}_{\text{fin}} \). Since \( P(\kappa) \) is indecomposable of dimension \( p \), it follows that \( H/I \) is not semisimple. Thus, the Hopf algebra \( H/I \) is a proper quotient, and it
must have dimension $p^2$ as all other possibilities (being $2$, $p$, or $2p$) are semisimple Hopf algebras (cf. [22, 34]). It follows, by [20], that $H/I \cong T_p$, where $T_p$ is a Taft algebra of dimension $p^2$. By Proposition 1.3, we have an exact sequence of Hopf algebras as follows:

$1 \rightarrow k[Z_2] \rightarrow H \rightarrow T_p \rightarrow 1$.

Dualizing this sequence, we get the exact sequence as follows:

$1 \rightarrow T_p \rightarrow H^* \rightarrow k[Z_2] \rightarrow 1$

since both $T_p$ and $k[Z_2]$ are self-dual. It is well known that the Jacobson radical $J$ of the Taft algebra $T_p$ is a Hopf ideal, and $T_p/J \cong k[Z_p]$. Applying Proposition 1.7, we find that $H$ contains a semisimple Hopf subalgebra $K$ of dimension $2p$. Since $S^{2p} = \text{id}_H$, Proposition 5.1 in [2] implies that $K$ is the coradical of $H$. It follows immediately by [1, Lemma A.2] that $H$ is pointed.

Combining Lemmas 3.1–3.4, we complete the proof of our main result, Theorem I.

Appendix

The following lemma was used in [23, Lemmas 1.4, 2.2]. We believe the result is known but we provide a proof for the sake of completeness.

**Lemma A.1.** Let $A$ be an algebra over an algebraically closed field $k$ and let $\sigma$ be a diagonalizable (or semisimple) algebra automorphism on $A$. If $V$ is a finite-dimensional $A$-module that is isomorphic to $\sigma V$, then there exists an isomorphism of $A$-modules $\phi : V \rightarrow \sigma V$ such that $\phi$ is diagonalizable.

**Proof.** Let $\psi : V \rightarrow \sigma V$ be an isomorphism of $A$-modules and let $\rho : A \rightarrow \text{End}_k(V)$ be the representation of $A$ associated with the $A$-module $V$. Then we have

$\psi \circ \rho(a) = \rho(\sigma(a)) \circ \psi$ for all $a \in A$.

Suppose that $a \in A$ is an eigenvector of $\sigma$ corresponding to the eigenvalue $\gamma$ such that $\rho(a) \neq 0$. Then we have $C_{\psi_{\gamma}}(\rho(a)) = \gamma \rho(a)$, where $C_{\psi_{\gamma}} : \text{End}_k(V) \rightarrow \text{End}_k(V)$ is defined by $g \mapsto \psi_{\gamma} \circ g \circ \psi_{\gamma}^{-1}$. In particular, $\rho(a)$ is an eigenvector of $C_{\psi_{\gamma}}$. If $\psi = \psi_{\gamma} \circ \psi_u$ is the Jordan–Chevalley decomposition of $\psi$ with $\psi_{\gamma}$ being the semisimple part and $\psi_u$ the unipotent part of $\psi$, then $C_{\psi_{\gamma}}$ is diagonalizable, $C_{\psi_u}$ is unipotent, and $C_{\psi} = C_{\psi_{\gamma}} \circ C_{\psi_u}$ is the Jordan–Chevalley decomposition of $C_{\psi}$. Thus, $C_{\psi_{\gamma}}(\rho(a)) = \gamma \rho(a)$ or

$\psi_{\gamma} \circ \rho(a) = \rho(\sigma(a)) \circ \psi_{\gamma}$.

Since $\sigma$ is diagonalizable, this equality holds for all $a \in A$. Therefore, $\psi_{\gamma}$ is our desired isomorphism of $A$-modules.

For the purpose of this paper and future development, we need to establish a more general version of a part of the results obtained in [23, Lemmas 1.4, 2.2(i)].

**Lemma A.2.** Let $A$ be a finite-dimensional algebra over an algebraically closed field $k$ of characteristic zero and let $\sigma$ be an algebra automorphism on $A$ of order $n$. If $V$ is a finite-dimensional indecomposable $A$-module that is isomorphic to $\sigma V$, then there exists an isomorphism of $A$-modules $\phi : V \rightarrow \sigma V$ such that $\phi^n = \text{id}_V$.
Proof. We simply extract the proof from [23, Lemma 1.4]. It follows, by Lemma A.1, that there exists a diagonalizable operator $\phi$ on $V$ such that $\phi(av) = \sigma(a)\phi(v)$ for $a \in A$ and $v \in V$. Thus, $\phi^n$ is an $A$-module automorphism on $V$. Since $\text{End}_A(V)$ is a finite-dimensional local $k$-algebra, it follows that $\phi^n = c \cdot \text{id}_V$ for some non-zero scalar $c$. Therefore, if we take $t \in k$ to be an $n$th root of $c$, then $(1/t)\phi$ is a desired $A$-module isomorphism.

Acknowledgements. The authors would like to thank Akira Masuoka for his invaluable suggestion on the proof of Proposition 1.7, and Susan Montgomery for her suggestion of several references. The second author also thanks the National Center for Theoretical Sciences in Taiwan, where the present work was carried out, for the generous hospitality, and Ching-Hung Lam for being a wonderful host.
