A well-known result of Tutte is that $U_{2,4}$, the 4-point line, is the only non-binary matroid $M$ such that, for every element $e$, both $M\setminus e$ and $M/e$, the deletion and contraction of $e$ from $M$, are binary. This paper characterizes those non-binary matroids $M$ such that, for every element $e$, $M\setminus e$ or $M/e$ is binary. © 1990 Academic Press, Inc.

1. Introduction

The class of binary matroids is one of the best-known and most frequently studied classes of matroids. In this paper, we characterize a class of non-binary matroids that are, in a certain natural sense, close to being binary. Tutte [11] proved that $U_{2,4}$ is the only non-binary matroid for which every single-element deletion and every single-element contraction is binary. Here we characterize a larger class of non-binary matroids: those such that, for every element $e$, the deletion or the contraction of $e$ is binary.

Most of the matroid terminology used here will follow Welsh [13]. The ground set, corank, and rank function of the matroid $M$ will be denoted by $E(M)$, $	ext{cork } M$, and $	ext{rk } M$, respectively. If $T \subseteq E(M)$, we shall say that $M$ uses $T$. We shall denote by $M\setminus T$ or $M\lfloor(E(M)-T)$ the deletion of $T$ from $M$, and by $M/T$ the contraction of $T$ from $M$.

Let $n$ be a positive integer. The matroid $M$ is $n$-connected [12] if, for all positive integers $k < n$, there is no partition $\{S, T\}$ of $E(M)$ such that $|S|, |T| \geq k$ and $\text{rk } S + \text{rk } T - \text{rk } M = k - 1$. Thus a matroid is 2-connected precisely when it is connected [13, p. 69]. Moreover, it is easy to show that $M$ is $n$-connected if and only if $M^*$ is $n$-connected.

* This research was partially supported by a grant from the Louisiana Education Quality Support Fund through the Board of Regents.
For matroids $M_1$ and $M_2$ such that $E(M_1) \cap E(M_2) = \{p\}$, we denote the series and parallel connections of $M_1$ and $M_2$ with respect to the basepoint $p$ by $S(M_1, M_2)$ and $P(M_1, M_2)$. If both $E(M_1)$ and $E(M_2)$ have at least three elements and $p$ is neither a loop nor a coloop of $M_1$ or $M_2$, then the 2-sum of $M_1$ and $M_2$ is $P(M_1, M_2) \setminus p$, or equivalently, $S(M_1, M_2)/p$. We call $M_1$ and $M_2$ the parts of this 2-sum. One attractive feature of this operation is that the dual of the 2-sum of $M_1$ and $M_2$ is the 2-sum of $M_1^*$ and $M_2^*$. Seymour [8, (2.6)] (see also [1, 3]) proved the following basic link between 3-connectedness and 2-sums.

(1.1) Lemma. A connected matroid $M$ is not 3-connected if and only if there is a pair of matroids such that $M$ is their 2-sum.

We shall assume familiarity with other basic properties of 2-sums. Those needed here are summarized in [5, p. 664].

If $\{x, y\}$ is a circuit of the matroid $M$, we say that $x$ and $y$ are in parallel in $M$. If $\{x, y\}$ is a cocircuit, then $x$ and $y$ are in series. A parallel class of $M$ is a maximal subset $A$ of $E(M)$ such that if $a$ and $b$ are distinct members of $A$, then $a$ and $b$ are in parallel. Series classes are defined analogously. A series or parallel class is non-trivial if it contains more than one element. The matroid $N$ is a series extension of $M$ if $M = N/\mathcal{T}$ and every element of $\mathcal{T}$ is in series with some element of $M$. We call $N$ a parallel extension of $M$ if $N^*$ is a series extension of $M^*$.

The main results of this paper use the following basic construction. Let $C$ be a circuit-hyperplane of the matroid $M$, that is, $C$ is both a circuit and a hyperplane of $M$. Let $\mathcal{B} = \{B: B$ is a basis of $M\} \cup \{C\}$. Then it is well known (see, for example, [7, p. 164; 9, p. 77]) that $\mathcal{B}$ is the set of bases of a matroid $M'$ on $E(M)$. Following Kahn [4], we call $M'$ a relaxation of $M$. We shall also say that $M'$ has been obtained from $M$ by relaxing the circuit-hyperplane $C$. Thus, for example, the non-Fano and non-Pappus matroids are relaxations of the Fano and Pappus matroids, respectively. Moreover, the whirl $\mathcal{W}^{r'}$ [13, p. 81] is a relaxation of $M(\mathcal{W})$, the cycle matroid of the $r$-spoked wheel.

The next two theorems are the main results of the paper. Although the second is weaker than the first, we state both since the proof of the second is a major step in the proof of the first.

(1.2) Theorem. The following two statements are equivalent for a matroid $M$.

(i) $M$ is non-binary and, for every element $e$, $M \setminus e$ or $M/e$ is binary.

(ii) (a) Both $\text{rk } M$ and $\text{cork } M$ exceed two and $M$ can be obtained from a connected binary matroid by relaxing a circuit-hyperplane; or
(b) \( M \) is isomorphic to a parallel extension of \( U_{2,n} \) for some \( n \geq 5 \); or
(c) \( M \) is isomorphic to a series extension of \( U_{n-2,n} \) for some \( n \geq 5 \); or
(d) \( M \) can be obtained from \( U_{2,4} \) by series extension of a subset \( S \) of \( E(U_{2,4}) \) and parallel extension of a disjoint subset \( T \) of \( E(U_{2,4}) \) where \( S \) or \( T \) may be empty.

(1.3) THEOREM. The following two statements are equivalent for a matroid \( M \).

(i) \( M \) is non-binary, 3-connected, and, for every element \( e \), \( M \setminus e \) or \( M/e \) is binary.

(ii) (a) \( M \) is isomorphic to \( U_{2,n} \) or \( U_{n-2,n} \) for some \( n \geq 4 \); or
    (b) both the rank and corank of \( M \) exceed two and \( M \) can be obtained from a 3-connected binary matroid by relaxing a circuit–hyperplane.

The proofs of these theorems will be given in Section 2. In the remainder of this section, we note some preliminaries that will be needed in the proofs. We begin with a number of properties of relaxation that were noted by Kahn [4, p. 320].

(1.4) LEMMA. Suppose that \( M_2 \) is obtained from \( M_1 \) by relaxing the circuit–hyperplane \( C \). Then

(i) \( M_2^* \) is obtained from \( M_1^* \) by relaxing the circuit–hyperplane \( E(M_1) - C \);
(ii) if \( a \in C \) and \( b \in E(M) - C \), then \( M_2 \setminus a = M_1 \setminus a \) and \( M_2/b = M_1/b \);
(iii) if \( M_1 \) is n-connected, then so is \( M_2 \); and
(iv) if \( M_1 \) is connected, then \( M_2 \) is non-binary.

The following result enables one to recognize when a matroid is a relaxation of another matroid. The straightforward proof is omitted.

(1.5) LEMMA. Let \( M \) be a matroid having rank at least one and \( Y \) be a basis of \( M \). Suppose that, for all \( e \) in \( E(M) - Y \), the fundamental circuit of \( e \) with respect to \( Y \) is \( Y \cup e \). Then

\[
\{Z: Z \text{ is a circuit of } M\} - \{Y \cup e: e \in E(M) - Y\} \cup \{Y\}
\]

is the set of circuits of a matroid \( N \) on \( E(M) \). Moreover, \( Y \) is a hyperplane of \( N \) and \( M \) is obtained from \( N \) by relaxing \( Y \).

The next two lemmas are structural results for non-binary 3-connected
matroids. Figure 1 gives Euclidean representations for the matroids $P_6$ and $Q_6$ that appear in the second of these.

(1.6) **Lemma** [9, (3.1)]. If $x$ and $y$ are elements of a non-binary 3-connected matroid $M$, then $M$ has a $U_{2,4}$-minor using $\{x, y\}$.

(1.7) **Lemma** [5, Theorem 3.1]. Let $M$ be a non-binary 3-connected matroid having rank and corank at least three. Then $M$ has a minor isomorphic to one of $U_{3,6}, P_6, Q_6, \text{ or } \mathbb{W}^3$.

Theorem 1.2 contains one generalization of Tutte's excluded-minor characterization of binary matroids [11]. The following is an alternative generalization of that result.

(1.8) **Lemma.** Let $M$ be a non-binary matroid such that, for some element $e$, both $M\setminus e$ and $M/e$ are binary. Then $M$ is obtained from a 4-point line having ground set $\{e, e_1, e_2, e_3\}$ by a sequence of at most three 2-sums where the basepoints of these 2-sums are $e_1, e_2,$ and $e_3,$ the other part of each 2-sum is binary, and each of $e_1, e_2,$ and $e_3$ is the basepoint of at most one of these 2-sums.

**Proof.** Evidently we may assume that $M$ is connected. The lemma is now immediate from [5, Theorem 3.8].

As an immediate consequence of the last result, we have the following:

(1.9) **Corollary** [5, Corollary 3.9]. If $M$ is 3-connected, non-binary and, for some element $e$, both $M\setminus e$ and $M/e$ are binary, then $M \cong U_{2,4}$.

2. **The Proofs**

In this section, we prove Theorems 1.2 and 1.3, beginning with the latter.

**Proof of Theorem 1.3.** Assume that (ii) holds. If $M \cong U_{2,n}$ or $U_{n-2,n}$ for some $n \geq 4$, then (i) holds. Now suppose that both the rank and corank of $M$ exceed two and that $M$ is obtained from a binary 3-connected matroid

![Diagram](figure1.png)

**Figure 1**
A CLASS OF NON-BINARY MATROIDS

by relaxing a circuit-hyperplane \( C \). Then, by Lemma 1.4(iii) and (iv), \( M \) is 3-connected and non-binary. Moreover, by Lemma 1.4(ii), if \( e \in C \), then \( M \setminus e \) is binary, while if \( e \in E(M) - C \), then \( M/e \) is binary. We conclude that (ii) implies (i).

Now suppose that (i) holds. Evidently, if \( \text{rk} \ M = 2 \) or \( \text{cork} \ M = 2 \), then, as \( M \) is 3-connected, it is isomorphic to \( U_{2,n} \) or \( U_{n-2,n} \) for some \( n \geq 4 \). Thus we may assume that both the rank and corank of \( M \) exceed two.

Suppose that \( \text{rk} \ M = 3 \). Then, by Lemma 1.7, \( M \) has a minor isomorphic to one of \( U_{3,6}, P_6, Q_6, \) or \( \mathcal{W}^3 \). In the first three cases, if the element \( e \) is as marked in Fig. 2, then both \( M \setminus e \) and \( M/e \) are non-binary. We conclude that \( M \) has a \( \mathcal{W}^3 \)-minor, but has no minor isomorphic to \( U_{3,6}, P_6, \) or \( Q_6 \). Using this and the fact that, for all elements \( e \) of \( M \), \( M \setminus e \) or \( M/e \) is binary, it is not difficult to check that \( M \) is isomorphic to \( \mathcal{W}^3 \) or the non-Fano matroid. As these matroids are relaxations of \( M(\mathcal{W}_3) \) and the Fano matroid, respectively, the theorem holds if \( \text{rk} \ M = 3 \). By duality, it also holds if \( \text{cork} \ M = 3 \).

We now assume that both \( \text{rk} \ M \) and \( \text{cork} \ M \) exceed three. Let \( X = \{ x \in E(M) : M \setminus x \text{ is non-binary} \} \) and \( Y = \{ y \in E(M) : M/y \text{ is non-binary} \} \). By Corollary 1.9, \( X \cup Y = E(M) \) and, by hypothesis, \( X \cap Y = \emptyset \).

(2.1) LEMMA. \( Y \) is a basis and \( X \) is a cobasis of \( M \).

Proof. As \( \{ X, Y \} \) is a partition of \( E(M) \), it suffices to show that \( Y \) is a basis. Since \( M \) is non-binary, for some pair, \( A \) and \( D \), of disjoint subsets of \( E(M) \), \( M \setminus A/D \cong U_{2,4} \). Evidently \( D \subseteq Y \) and \( A \subseteq X \). Moreover, as \( X \cap Y = \emptyset \), we may assume that \( D \) is independent and \( A \) is coindependent in \( M \).

Since \( \text{rk} \ M \) and \( \text{cork} \ M \) exceed three, we can choose 2-element subsets \( \{ d_1, d_2 \} \) and \( \{ a_1, a_2 \} \) of \( D \) and \( A \), respectively. By Lemma 1.6, \( M \) has \( U_{2,4} \)-minors \( M \setminus A'/D' \) and \( M \setminus A''/D'' \) that use \( \{ d_1, d_2 \} \) and \( \{ a_1, a_2 \} \), respectively. Since \( X \cap Y = \emptyset \), both \( D' \) and \( A'' \) contain at least two elements of \( E(M) - (A \cup D) \), and \( D' \cap A'' = \emptyset \). Thus exactly two elements, say \( e_1 \) and \( e_2 \), of \( E(M) - (A \cup D) \) are in \( Y \) and the other two elements are in \( X \). Since \( D \) and \( \{ e_1, e_2 \} \) are bases of \( M \mid D \) and \( M/D \), respectively, \( D \cup \{ e_1, e_2 \} \) is a basis of \( M \). Since \( D \cup \{ e_1, e_2 \} = Y \), the lemma holds. \( \blacksquare \)
We shall show next that it is the set \( Y \) whose relaxation produces the matroid \( M \).

(2.2) **Lemma.** For all \( e \) in \( X \), the fundamental circuit \( C(e, Y) \) is \( Y \cup e \).

**Proof.** Suppose that, for some element \( e \) of \( X \), the fundamental circuit \( C(e, Y) \) does not contain \( Y \). Then we can choose an element \( y_1 \) from \( Y - C(e, Y) \). Let \( y_2 \) be an element of \( Y - y_1 \). By Lemma 1.6, \( M \) has a \( U_{2,4} \)-minor \( M\backslash Z_1/Z_2 \) using \( \{ y_1, y_2 \} \). Evidently \( Z_2 \subseteq Y \) and \( |Z_2| = \text{rk} \ M - 2 = |Y| - 2 \). Therefore \( Z_2 = Y - \{ y_1, y_2 \} \). Thus, in \( M/Z_2 \), there are two possibilities: either (I) \( e \) is a loop, or (II) \( e \) is parallel to \( y_2 \). In the first case, \( M/Z_2/e \), and hence, \( M/e \) is non-binary, contrary to the fact that \( e \in X \). In case II, \( M/Z_2 \backslash y_2 \) has a \( U_{2,4} \)-minor, contrary to the fact that \( y_2 \in Y \). We conclude that the lemma holds. \( \blacksquare \)

Now define the collection \( \mathcal{C} \) to be

\[
\left\{ Z : Z \text{ is a circuit of } M \right\} - \left\{ Y \cup e : e \in X \right\} \cup \{ Y \}.
\]

Then, by Lemma 1.5, \( \mathcal{C} \) is the set of circuits of a matroid \( N \) on \( E(M) \) and \( Y \) is a hyperplane of \( N \). Moreover, \( M \) is obtained from \( N \) by relaxing the circuit–hyperplane \( Y \). By Lemma 1.4(i), \( M^* \) is obtained from \( N^* \) by relaxing the circuit–hyperplane \( X \) of \( N^* \). Thus the set of cocircuits of \( N \) is

\[
\left\{ Z^* : Z^* \text{ is a cocircuit of } M \right\} - \left\{ X \cup f : f \in Y \right\} \cup \{ X \}.
\]

The next two lemmas complete the proof that (i) implies (ii) by showing that \( N \) is 3-connected and binary.

(2.3) **Lemma.** \( N \) is 3-connected.

**Proof.** Suppose that \( N \) is not 3-connected. Then, as \( E(N) = E(M) \), for some \( k \) in \( \{ 1, 2 \} \), there is a partition \( \{ S, T \} \) of \( E(M) \) such that \( |S|, |T| \geq k \) and

\[
\text{rk}_N(S) + \text{rk}_N(T) - \text{rk} \ N = k - 1. \tag{2.4}
\]

Now, all subsets of \( E(M) \) except \( Y \) have the same rank in \( N \) as they do in \( M \), while \( \text{rk}_N(Y) = \text{rk} \ N - 1 \). Thus, as \( M \) is 3-connected, (2.4) implies that \( S \) or \( T \), say \( T \), equals \( Y \). Hence, \( S = X \) and \( \text{rk}_M X = k \). As \( |X| \geq 4 \) and \( M \) is 3-connected, \( k \neq 1 \). Hence \( k = 2 \). Thus, in \( M \), the set \( X \) is a cobasis contained in a line \( L \) that has at least four points. Now, since \( \text{rk} \ M \geq 4 \), there is an element \( y \) of \( M \) not in \( L \). As \( M \backslash y \) has a \( U_{2,4} \)-minor, it is non-binary. But \( y \notin X \) and so we have a contradiction that completes the proof of the lemma. \( \blacksquare \)

(2.5) **Lemma.** \( N \) is binary.
**Proof.** Assume that $N$ is non-binary. Then, by a well-known result of Seymour [6, p. 360], $N$ has a circuit $C$ and a cocircuit $C^*$ such that $|C \cap C^*| = 3$. Now $C$ is a circuit of $M$ unless $C = Y$, and $C^*$ is a cocircuit of $M$ unless $C^* = X$. As $X$ and $Y$ are disjoint, we cannot have both $C = Y$ and $C^* = X$.

Suppose that $C = Y$. Then $C^*$ is a cocircuit of $M$ and is not equal to $X$. Hence $C^* \not\subseteq X$, so we can choose an element $x$ from $X - C^*$. Now $Y \cup x$ is a circuit of $M$ meeting $C^*$ in exactly three elements. Thus $M/x$ is non-binary because $Y$ and $C^*$ are a circuit and a cocircuit of it that meet in exactly three elements. But, since $x \in X$, this is a contradiction. Therefore $C \neq Y$ and, by duality, $C^* \neq X$. Hence $C$ is a circuit of $M$ and $C^*$ is a cocircuit of $M$.

Suppose $y \in C - C^*$. Then $C - y$ is a circuit and $C^*$ is a cocircuit of $M/y$. Thus $M/y$ is non-binary and so $y \in Y$. Hence $C - C^* \subseteq Y$, and, by duality, $C^* - C \subseteq X$. Consider $C \cap C^*$. As $C \not\subseteq Y$ and $C^* \not\subseteq X$, neither $C \cap C^* \cap X$ nor $C \cap C^* \cap Y$ is empty. Since $|C \cap C^*| = 3$, it follows that $|C \cap C^* \cap X|$ or $|C \cap C^* \cap Y|$ is 1. By duality, we may assume the former. Let $C \cap C^* \cap X = \{z\}$. Then $C \subseteq Y \cup z$. But $Y \cup z$ is a circuit of $M$. Hence $C = Y \cup z$ and so $C$ is not a circuit of $N$. This contradiction completes the proof of Lemma 2.5 and thereby that of Theorem 1.3.

**Proof of Theorem 1.2.** We omit the straightforward argument showing that if (ii) holds, then so does (i). Now assume that (i) holds. We argue by induction on $|E(M)|$ to show that (ii) holds. If $M$ is 3-connected, then the result follows easily from Theorem 1.3. Assume the result is true for all matroids having fewer elements than $M$. It is straightforward to check that $M$ must be connected. Hence, as $M$ is connected but not 3-connected, Lemma 1.1 implies that, for some matroids $M_1$ and $M_2$ with $E(M_1) \cap E(M_2) = \{p\}$, $M = P(M_1, M_2) \setminus p$ where $|E(M_1)|, |E(M_2)| \geq 3$. Now $M_1$ or $M_2$ is non-binary. Without loss of generality, assume the former.

(2.6) **Lemma.** $M_2$ is isomorphic to $U_{1,n}$ or $U_{n-1,n}$ for some $n \geq 3$.

**Proof.** Since $M$ is connected, so is $M_2$. For each $x$ in $E(M_2) - p$, let $C_x$ and $C^*_x$ be a maximum-sized circuit and a maximum-sized cocircuit of $M_2$ containing $\{p, x\}$. If both $|C_x|$ and $|C^*_x|$ exceed two, then both $M \setminus x$ and $M/x$ have $M_1$ as a minor, so both are non-binary, a contradiction. Thus, for all $x$ in $E(M_2) - p$, $|C_x| = 2$ or $|C^*_x| = 2$. If $x$ and $y$ are distinct elements of $E(M_2) - p$ and $|C_x| = 2 = |C^*_y|$, then $C_x \cap C^*_y = \{p\}$, a contradiction. Thus either $|C_x| = 2$ for all $x$ in $E(M_2) - p$, or $|C^*_x| = 2$ for all such $x$. The lemma follows immediately.

By the last lemma, we may assume that $M_2 \cong U_{1,n}$ for some $n \geq 3$, otherwise we replace $M$ by $M^*$ in the argument that follows. We may also
suppose that $M_1$ has no elements in parallel with $p$, since any such element can be taken to be in $M_2$ rather than in $M_1$. Thus $M$ is obtained from $M_1$ by replacing $p$ by $n - 1$ elements in parallel.

(2.7) **Lemma.** For all $e$ in $E(M_1)$, $M_1 \setminus e$ or $M_1 / e$ is binary.

**Proof.** If $e \neq p$, then, by [2, Propositions 4.7 and 5.6], $M_1 \setminus e = P(M_1 \setminus e, M_2) \setminus p$ and $M_1 / e = P(M_1 / e, M_2) \setminus p$. Since $M_1 \setminus e$ or $M_1 / e$ is binary and $M_2$ is also binary, it follows that $M_1 \setminus e$ or $M_1 / e$ is binary. Now suppose that $e = p$. Pick an element $q$ of $E(M_2) - p$. Then $M \setminus q$ is non-binary, so $M / q$ is binary. But $M / q \cong M_1 / p \oplus U_{0,n-2}$. Hence

\[ M_1 / p \text{ is binary.} \]

(2.8)

We conclude that Lemma 2.7 holds. 

By the induction assumption, one of (ii)(a)-(d) holds for $M_1$. Suppose (ii)(a) holds, that is, both $rk M_1$ and $cork M_1$ exceed two, and $M_1$ can be obtained from a connected binary matroid $N_1$ by relaxing a circuit–hyperplane $C$. If $p \notin C$, then $M$ is isomorphic to the matroid obtained from $M_1$ by adjoining $n - 2$ elements in parallel with $p$. If we adjoin $n - 2$ elements in parallel with $p$ in $N_1$, we get a connected binary matroid $N_2$ that still has $C$ as a circuit–hyperplane. It is not difficult to check that $M$ is isomorphic to the matroid obtained from $N_2$ by relaxing $C$. Thus if $p \notin C$, then (ii)(a) holds for $M$. We may therefore assume that $p \in C$. Then, by Lemma 1.4(ii), $M_1 \setminus p = N_1 \setminus p$. Hence $M_1 \setminus p$ is binary. In addition, by (2.8), $M_1 / p$ is binary. Therefore, by Lemma 1.8, $M_1$ can be obtained from $U_{2,4}$ by a sequence of at most three 2-sums. By Lemma 2.6, one part of each of these 2-sums is either a rank-one uniform matroid or a corank-one uniform matroid. We conclude that if $M_1$ satisfies (ii)(a), then $M$ satisfies (ii)(d).

If $M_1$ satisfies (ii)(b), then, clearly, so does $M$. We may now suppose that $M_1$ satisfies (ii)(c) or (ii)(d). If $p$ is in a non-trivial series class, then, since $M_1$ is non-binary, so is $M_1 / p$, a contradiction to (2.8). Thus we may assume that $p$ is not in a non-trivial series class. It follows that if $M_1$ satisfies (ii)(c), then $M_1 / p$ is isomorphic to a series extension of $U_{n-3,n-1}$, and again (2.8) is contradicted. Hence we may suppose that $M_1$ satisfies (ii)(d). Then, by the choice of $M_2$, the element $p$ is not in a non-trivial parallel class of $M_1$. Thus $p$ is an element of $U_{2,4}$ that is not involved in any of the series and parallel extensions used to form $M_1$. We conclude that $M$ satisfies (ii)(d), thereby completing the proof of Theorem 1.2.
