Abstract

Our object of study is relative quadratic extensions of algebraic number fields $F/K = K(\sqrt{\sigma})/K$, with $\sigma \in K^* \backslash K^{*2}$. In [4], the authors P.E. Conner and J. Hurrelbrink study in detail the cases $\sigma$ totally positive respectively totally negative. In this paper we generalize some of the results without any assumption on the sign of $\sigma$. 
Introduction

In this paper we study relative quadratic extensions of algebraic number fields $F/K$. Using a unified approach, we shall deal with classical questions concerning the interplay between units, ideal class groups of $F$ and $K$, and ramification in $F/K$. In their book [4], P.E. Conner and J. Hurrelbrink give a detailed treatment of $F = K(\sqrt{\sigma})/K$ when $\sigma$ is totally positive or totally negative. We shall extend these results to any relative quadratic extension $F/K$.

Our main tool is the exact hexagon 1.18 which involves four cohomology groups $H^s(\text{Gal}(F/K); O_F^*), H^s(\text{Gal}(F/K); C(F))$ and two computable groups $R^s(F/K), s = 0, 1$.

In order to do this, we introduce for any number field $L$ and its ring of integers $\mathcal{O}_L$, the ideal class group of $L$, denoted $C(L)$.

Let $J$ be the group of nonzero fractional $\mathcal{O}_L$-ideals and $H$ the subgroup of nonzero principal fractional $\mathcal{O}_L$-ideals. Then $C(L)$ is the quotient group $J/H$. The group $C(L)$ is trivial if and only if $\mathcal{O}_L$ is a principal ideal domain (PID) and thus we have unique prime element decomposition. For any number field $L$, $C(L)$ is a finite abelian group. The number of elements in $C(L)$ is the class number of $L$, denoted by $h(L)$. It is a classical problem to investigate the structure and order of the ideal class group.

Gauss knew for squarefree $d < 0$ that there are at least nine fields $\mathbb{Q}(\sqrt{d})$ with class number 1. Heilbronn and Linfoot [19] in 1934 showed that the class number is 1 for at most one more such $d$. It was finally proved that there are only nine such fields with class number 1, first by Heegner [18] in 1952, then independently
by Baker [1] and Stark [48] in 1966. All number fields with class number 2 were characterized by Carlitz [3].

To understand the structure of the ideal class group for a quadratic number field, it is important to determine the structure of its 2-Sylow subgroup. As the ideal class group $C(L)$ of $L$ is a finite abelian group, it is a product of cyclic groups of prime power order. The 2-rank of $C(L)$ is the number of cyclic factors of $C(L)$ of order divisible by 2. We note that this notion of 2-rank holds for any finite abelian group. Using quadratic forms, Gauss proved that the 2-rank of the (narrow) ideal class group of $L$ is $t - 1$ where $t$ is the number of distinct prime divisors of the discriminant of $L$. As a consequence, we have:

**Proposition 0.1.** 2-rank $(C(L)) = t - 2$ if $L$ is real quadratic and $-1$ is not a norm from $L$, and $t - 1$ otherwise.

In Chapter 2 we extend this result to a relative quadratic extension and prove the following, see Theorem 2.43

**Theorem 0.2.** Let $K$ be a totally real algebraic number field containing units with independent signs, and $F/K$ a quadratic extension of $K$. If $h(K) \equiv 1 \pmod{2}$ and $O_F^*$ contains units with independent signs, then

$$2\text{-rk } (C(F)) = \#R(F/K) - 1$$

where $\#R(F/K)$ represents the number of ramified prime ideals in $F/K$.

For a number field $F$ and its ring of integers $O_F$, the units of $O_F$ are the elements $u \in O_F$ such that there exists $x \in O_F$ with $ux = 1$. The units form a multiplicative group, denoted $O_F^*$. Consider the quadratic number field $F = \mathbb{Q}(\sqrt{d})$, $d \in \mathbb{Z}$, squarefree, and its ring of integers $O_F$. For an imaginary quadratic number field $F$, we have
Proposition 0.3. If $d < 0$ and squarefree, then

(i) For $d = -1$, $\mathcal{O}_F^* = \{\pm 1, \pm i\}$

(ii) For $d = -3$, $\mathcal{O}_F^* = \{\pm 1, \pm \omega, \pm \omega^2\}$ where $\omega = \frac{-1 + \sqrt{-3}}{2}$.

(iii) Otherwise, $\mathcal{O}_F^* = \{\pm 1\}$

Determining $\mathcal{O}_F^*$ in the case of a real quadratic field $F$ relies on the fact that the Pell equation

$$x^2 - dy^2 = \pm 1$$

has a solution in nonzero integers $x, y$. Using this result, one obtains

Proposition 0.4. If $\mathcal{O}_F$ is the ring of integers in $F = \mathbb{Q}(\sqrt{d})$, $d > 0$ and squarefree, then there exists a unit $\epsilon > 1$ such that every unit of $\mathcal{O}_F$ is of the form $\pm \epsilon^m$, $m \in \mathbb{Z}$.

The unique unit $\epsilon$ is called the fundamental unit of $\mathbb{Q}(\sqrt{d})$. For a real quadratic field $F$, Dirichlet related the class number $h(F)$ and the fundamental unit of $F$. Propositions 0.3 and 0.4 are very special cases of Dirichlet’s Unit Theorem which gives the structure of the group of units in a number field.

A very important question is when does a field $F$ have units with independent signs. In [4] the authors prove the following

Proposition 0.5. Let $K$ be totally real and $F/K$ a real quadratic extension. Then $F$ has units with independent signs if and only if $K$ has units with independent signs and $H^0(C_2; \mathcal{O}_F^*)$ is trivial.

We shall generalize this and prove that, see Corollary 2.36

Proposition 0.6. Let $K$ be totally real, having units with independent signs and $F = K(\sqrt{\sigma})/K$. Denote by $n = [K : \mathbb{Q}]$ and by $0 \leq k \leq n$ the number of real
embeddings of $K$ with respect to which $\sigma$ is positive. If $\sigma \notin O_K^*/O_K^{*2}$ then the following are equivalent:

1. $F$ contains units with independent signs.

2. $2 \cdot \text{rk} H^0(C_2; O_F^*) = n - k$.

3. Every unit of $O_K^*$ which is positive at every ordering of $K$ with respect to which $\sigma$ is negative, is the norm of a unit in $O_F^*$.

4. $H^1(C_2; O_F^*)$ is cyclic of order 2 (generated by $\text{cl}(-1)$).

Example 0.7. Let $p$ be a prime. The structure of the 2-Sylow subgroup of the ideal class group of the real quadratic fields $\mathbb{Q}(\sqrt{2p})$ is given by:

\begin{align*}
    p &= 2 : \{1\} \\
    p &\equiv 3, 7 \mod 8 : \{1\} \\
    p &\equiv 1 \mod 8 : C_2 \text{ if } p \neq x^2 + 32y^2 \text{ for all } x, y \in \mathbb{Z} \\
    &\quad : C_{2^j} \text{ for } j \geq 2 \text{ if } p = x^2 + 32y^2 \text{ for some } x, y \in \mathbb{Z} \\
    p &\equiv 5 \mod 8 : C_2.
\end{align*}

By Theorem 21.6 in [4], the sets $\{p \equiv 1 \mod 8 : p \neq x^2 + 32y^2 \forall x, y \in \mathbb{Z}\}$ and $\{p \equiv 1 \mod 8 : p = x^2 + 32y^2 \text{ for some } x, y \in \mathbb{Z}\}$ each have a density $\frac{1}{2}$ in the set of primes $p \equiv 1 \mod 8$.

In chapter 1, we introduce the notions and results which are necessary to prove our results. We also present the exact hexagon and the main results derived from its formalism.

In chapter 2, we prove the main results of our paper.

In chapter 3, we construct a finite extension of $\mathbb{Q}$ which will enable us to prove a density result via Chebotarev’s Density Theorem. In the end we present three
lists, obtained by using PariGP, that lead us to some conjectures about density results concerning the norm of fundamental units.
1. Basic Tools

1.1 Basic Results

In this section we will recall basic definitions and theorems that are going to be used in this paper. A *number field* is a subfield of \( \mathbb{C} \) which has finite degree over \( \mathbb{Q} \). We will denote this degree by \([K : \mathbb{Q}]\). For a number field \( K \) we let \( \mathcal{O}_K \) denote the *ring of algebraic integers of \( K \)*, namely the set of all \( x \in K \) which are roots of some monic polynomial with integer coefficients. Even though rings of integers are not unique factorization domains we can recover this feature by looking at the ideals of \( \mathcal{O}_K \):

**Theorem 1.8.** If \( K \) is a number field, then any nonzero ideal \( P \) of \( \mathcal{O}_K \) can be written uniquely, up to order, as a product of prime ideals.

Thus, if \( P = p_1 \cdot p_2 \cdots p_r \) is the prime decomposition of \( P \) then \( p_i \) are exactly the prime ideals of \( \mathcal{O}_K \) containing \( P \).

The *residue field* of the nonzero ideal \( P \) is the quotient ring \( \mathcal{O}_K/P \). This ring is finite and we define the *norm* of \( P \) to be \( N(P) = |\mathcal{O}_K/P| \). A very important thing to know is how primes are decomposing in finite extensions of number fields. Let \( K \) be a number field, and let \( F \) be a finite extension of \( K \). If \( P \) is a prime ideal of \( K \) then \( PO_F \) is an ideal of \( F \), and by Theorem 1.8 we have

\[ PO_F = Q_1^{e_1} \cdot Q_2^{e_2} \cdots Q_g^{e_g} \]

where the \( Q_i \)'s are distinct primes of \( F \) containing \( P \). The integer \( e_i \) is called the *ramification index* of \( P \) in \( Q \). We say that the prime ideal \( P \) of \( K \) is *ramified* in \( F \) if at least one \( e_i \) is greater than 1. If \( PO_F \) is prime in \( F \) then we say that \( P \) is *inert* in \( F \). The *inertial degree* \( f_i \) of \( P \) in \( Q \) is \([\mathcal{O}_F/Q_i : \mathcal{O}_K/P]\). Then we have the following

6
**Theorem 1.9.** Let $K \subset F$ be number fields, and let $P$ be a prime of $K$. If $e_i$ and $f_i$ are the ramification and inertial degrees respectively for $i = 1, 2, \ldots, g$, then

$$
\sum_{i=1}^{g} e_i f_i = [F : K].
$$

Assume that $K \subset F$ is a Galois extension. Then

**Theorem 1.10.** Let $K \subset F$ be a Galois extension, and let $P$ be a prime ideal of $K$. Then the Galois group $\text{Gal}(F/K)$ acts transitively on the primes of $F$ containing $P$. That is, if $Q$ and $Q'$ are primes of $F$ containing $P$, then there is a $\phi \in \text{Gal}(F/K)$ such that $\phi(Q) = Q'$.

If $F$ is a Galois extension of $K$ then Theorem 1.9 simplifies

**Theorem 1.11.** Let $K \subset F$ be a Galois extension and let $P$ be a prime if $K$. Then the primes $Q_1, Q_2, \ldots, Q_g$ of $F$ containing $P$ all have the same ramification index $e$, the same inertial degree $f$, and

$$
e f g = [F : K].$$

For a Galois extension $K \subset F$, an ideal $P$ of $K$ is ramified in $F$ if $e > 1$, and is unramified in $F$ if $e = 1$. We say that $P$ splits completely in $F$ if $e = f = 1$. If $P$ splits completely then it is also unramified and the number of primes in the decomposition of $P\mathcal{O}_F$ is $[F : K]$. Note that if $P$ is inert in $F$ then $g = e = 1$ and $f = [F : K]$. As an example let us consider quadratic number fields, i.e. fields of degree 2 over $\mathbb{Q}$. Let $K = \mathbb{Q}(\sqrt{d})$ with $d \neq 0, 1$ square free integer. The discriminant $d_K$ is given by

$$d_K = \begin{cases} 
  d & \text{if } d \equiv 1 \pmod{4} \\
  4d & \text{otherwise} 
\end{cases}$$

7
We also have that
\[ O_K = \begin{cases} 
\mathbb{Z} \left[ \frac{1+\sqrt{d}}{2} \right] & \text{if } d \equiv 1 \pmod{4} \\
\mathbb{Z} \left[ \sqrt{d} \right] & \text{otherwise}
\end{cases} \]

Let us now define the *Legendre symbol* \( \left( \frac{a}{p} \right) \). If \( a \) is an integer and \( p \) is an odd prime then
\[
\left( \frac{a}{p} \right) = \begin{cases} 
0 & \text{if } p \mid a \\
1 & \text{if } p \nmid a \text{ and } x^2 \equiv a \pmod{p} \text{ is solvable for some } x \in \mathbb{Z} \\
-1 & \text{if } p \nmid a \text{ and } x^2 \not\equiv a \pmod{p} \text{ for all } x \in \mathbb{Z}
\end{cases}
\]

Now we have the following

**Proposition 1.12.** Let \( a \) and \( b \) be integers and \( p \) an odd prime. Then

(i) \( a^{\frac{p-1}{2}} \equiv \left( \frac{a}{p} \right) \pmod{p} \)

(ii) \( \left( \frac{ab}{p} \right) = \left( \frac{a}{p} \right) \left( \frac{b}{p} \right) \)

(iii) If \( a \equiv b \pmod{p} \), then \( \left( \frac{a}{p} \right) = \left( \frac{b}{p} \right) \).

Let us now state one of the most beautiful results in mathematics

**Theorem 1.13.** *(Law of Quadratic Reciprocity)* Let \( p \) and \( q \) be odd primes. Then
\[ \left( \frac{p}{q} \right) \left( \frac{q}{p} \right) = (-1)^{\frac{p-1}{2} \frac{q-1}{2}}. \]

We can now describe the splitting behavior of primes of \( K \).

**Proposition 1.14.** Let \( p \) be an odd prime in \( \mathbb{Z} \) and \( K \) a quadratic number field of discriminant \( d_K \). Then

(i) If \( \left( \frac{d_K}{p} \right) = 0 \), then \( pO_K = P^2 \) for some ideal \( P \) of \( K \) (i.e. \( p \) ramifies in \( K \)).

(ii) If \( \left( \frac{d_K}{p} \right) = 1 \), then \( pO_K = PP' \) for some prime ideals \( P \neq P' \) of \( K \) (i.e. \( p \) splits completely in \( K \)).
(iii) If \( \left( \frac{d_K}{p} \right) = -1 \), then \( p\mathcal{O}_K \) is prime in \( \mathcal{O}_K \) (i.e. \( p \) is inert in \( K \)).

Another important result is the Dirichlet’s Unit Theorem:

**Theorem 1.15.** Let \( K \) be a number field, \( \mathcal{O}_K^\ast \) its unit group and denote by \( r_1(K) \) and \( 2r_2(K) \) the number of real and complex embeddings of \( K \) in \( \mathbb{C} \). Then \( \mathcal{O}_K^\ast \) is the direct product \( W \times V \) where \( W \) is a finite cyclic group consisting of the roots of unity in \( K \), and \( V \) is a free abelian group of rank \( r_1(K) + r_2(K) - 1 \).

In other words, \( V \) consists of products

\[
u_1^{k_1} \nu_2^{k_2} \cdots \nu_{r_1(K)+r_2(K)-1}^{k_{r_1(K)+r_2(K)-1}}, \quad k_i \in \mathbb{Z}
\]

for some set of \( r_1(K) + r_2(K) - 1 \) units. Note that if \( K \) is totally real, i.e. \( r_2(K) = 0 \), then \( V \) has rank \( r_1(K) - 1 \) and \( W = \{ \pm 1 \} \).

We will introduce the notion of **units with independent signs** which is related to the narrow class group of a number field \( K \).

**Definition 1.16.** A number field \( K \) has units with independent signs if and only if for each embedding \( \nu : K \to \mathbb{R} \) there is a unit in \( \mathcal{O}_K^\ast \) whose image under \( \nu \) is negative but whose image under every other real embedding of \( K \) is positive.

We note that if \( K \) has units with independent signs, then the sign homomorphism

\[
\mathcal{O}_K^\ast \to (\mathbb{Z}^\ast)^{r_1(K)}
\]

is an epimorphism. In [4] the authors prove the following result which we shall use later.

**Lemma 1.17.** Let \( K \) be a totally real number field. Then \( K \) has units with independent signs if and only if every totally positive unit in \( \mathcal{O}_K^\ast \) is a square.
1.2 The Exact Hexagon

We will follow [4] to define the exact hexagon. Let $F/K$ be a quadratic extension whose Galois group is cyclic of order 2. We will denote by $\bar{\cdot}$ the non trivial automorphism. Let us define two homomorphisms

$$d_0 : H^0(C_2; C(F)) \rightarrow H^0(C_2; \mathcal{O}_F^*)$$

and

$$d_1 : H^1(C_2; C(F)) \rightarrow H^1(C_2; \mathcal{O}_F^*)$$

in the following way.

An element of $H^0(C_2; C(F))$ is represented by some $\mathcal{O}_F$-ideal $A$ which satisfies $\bar{A} = xA$ for some $x \in F^*$. Then $A\bar{A} = \bar{x}xA\bar{A} = N(x)A\bar{A}$, hence $v = N(x) \in \mathcal{O}_K^*$. Set

$$d_0(\text{cl}(A)) = \text{cl}(v) \in H^0(C_2; \mathcal{O}_F^*).$$

An element of $H^1(C_2; C(F))$ is represented by some $\mathcal{O}_F$-ideal $A$ which satisfies $A\bar{A} = x\mathcal{O}_F$ for some $x \in F^*$. This time $x\mathcal{O}_F = A\bar{A} = \bar{A}\bar{A} = \bar{x}\mathcal{O}_F$, hence $u = \bar{x}x^{-1} \in \mathcal{O}_F^*$ and clearly $N(u) = 1$. Then set

$$d_1(\text{cl}(A)) = \text{cl}(u) \in H^1(C_2; \mathcal{O}_F^*).$$

Observe that to the extension $F/K$ there is an associated abelian group consisting of all pairs $(y, A)$ where $y \in K^*$ and $A$ is an $\mathcal{O}_F$-fractional ideal such that $yA\bar{A} = \mathcal{O}_F$. Now the group $R^0(F/K)$ is the quotient of this group of pairs $(y, A)$ by its subgroup consisting of pairs of the form $(N(z), z^{-1}\bar{B}B^{-1})$, where $z \in F^*$ and $B$ is an $\mathcal{O}_F$-fractional ideal. We denote by $\langle y, A \rangle$ the class of $(y, A)$ in the factor group $R^0(F/K)$. 

10
Now we are going to relate $R^0(F/K)$ to the cohomology groups $H^0(C_2; \mathcal{O}_F^*)$ and $H^1(C_2; C(F))$. We define

$$i_0 : H^0(C_2; \mathcal{O}_F^*) \to R^0(F/K)$$

by

$$\text{cl}(v) \mapsto \langle v, \mathcal{O}_F \rangle \text{ for } v \in \mathcal{O}_F^*.$$ 

Also, let us define

$$j_1 : R^0(F/K) \to H^1(C_2; C(F))$$

by

$$\langle y, A \rangle \mapsto \text{cl}(A) \text{ for } y \in K^*, \ yA\bar{A} = \mathcal{O}_F.$$ 

To define the group $R^1(F/K)$ we begin with the set of all pairs $(v, A)$ where $v \in \mathcal{O}_F^*$ is a unit with $N(v) = 1$ and $A$ is an $\mathcal{O}_F$-fractional ideal such that $\bar{A} = A$. This set is an abelian group with respect to component wise multiplication. We call two pairs $(v, A)$ and $(v_1, A_1)$ equivalent if there exist $x \in F^*$ and $B$ an $\mathcal{O}_F$-fractional ideal such that $xB\bar{B}A = A_1$ and $\bar{x}x^{-1}v = v_1$. It turns out that the above relation is an equivalence relation and we will denote the equivalence class of $(v, A)$ by $[v, A]$. Then the group $R^1(F/K)$ is defined as the set of all such equivalence classes $[v, A]$ with $v \in \mathcal{O}_F^*$, $N(v) = 1$, $A$ an $\mathcal{O}_F$-fractional ideal with $\bar{A} = A$.

We will connect $R^1(F/K)$ with the cohomology groups $H^1(C_2; \mathcal{O}_F^*)$ and $H^0(C_2; C(F))$ by defining two homomorphisms $i_1$ and $j_0$. First define

$$i_1 : H^1(C_2; \mathcal{O}_F^*) \to R^1(F/K)$$

by

$$\text{cl}(v) \mapsto [v, \mathcal{O}_F]$$

for $v \in \mathcal{O}_F^*$ with $N(v) = 1$. Secondly define

$$j_0 : R^1(F/K) \to H^0(C_2; C(F))$$
by

\[ |v, A| \mapsto \text{cl}(A) \]

for \( v \in \mathcal{O}_F^* \) with \( N(v) = 1 \) and \( A \) is an \( \mathcal{O}_F^* \)-fractional ideal with \( \bar{A} = A \).

Now Theorem 2.3 in [4] becomes

**Theorem 1.18.** Let \( F/K \) be a quadratic extension. Then there is an exact hexagon

\[
\begin{array}{c}
\text{H}^1(C_2; C(F)) \xrightarrow{d_1} \text{H}^1(C_2; \mathcal{O}_F^*) \\
\text{R}^0(F/K) \xrightarrow{i_0} \text{H}^0(C_2; \mathcal{O}_F^*) & \xrightarrow{d_0} \text{H}^0(C_2; C(F)) \\
\text{R}^1(F/K) \xleftarrow{j_0} \text{H}^0(C_2; \mathcal{O}_F^*) & \xleftarrow{j_1} \text{H}^1(C_2; C(F))
\end{array}
\]
2. Relative Quadratic Extensions

2.1 Definitions and Notations

We use as our base field a totally real number field $K$ containing units with independent signs. We let $n = [K : \mathbb{Q}]$ denote the absolute degree of $K$. Thus $n$ is the number of real infinite primes in $\Omega_K$; that is the number of distinct orderings of $K$.

Because $K$ is totally real it follows, by Lemma 1.17 that $K$ contains units with independent signs if and only if every totally positive unit in $\mathcal{O}_K^*$ is a square (and hence the square of a unit).

Let $C(K)$ denote the ideal class group of $K$. Then for the narrow class group of $K$ we have:

$$C^+(K) \cong C(K),$$

since $K$ contains units with independent signs.

Frequently we shall make use of the multiplicative group of global square classes $K^*/K^{*2}$. This is an elementary abelian 2-group.

Let us take up a simple example employing $K^*/K^{*2}$. First we denote by $E \subset K^*$ the subgroup of field elements $x \in K^*$ which satisfy the condition

$$\text{ord}_Px \equiv 0 \pmod{2}$$

at every prime ideal $P \subset \mathcal{O}_K$. Obviously $K^{*2} \subset E$ and $\mathcal{O}_K^* \subset E$. Then let us turn to the quotient group:

$$E = \mathcal{E}/K^{*2} \subset K^*/K^{*2}.$$ 

Since a unit in $\mathcal{O}_K^*$ is a square in $K^*$ if and only if it is a square in $\mathcal{O}_K^*$, then there is an inclusion

$$\mathcal{O}_K^*/\mathcal{O}_K^{*2} \subset E.$$ 

13
Next, if $C(K)_2 \subset C(K)$ is the subgroup of ideal classes with order less than or equal to 2, we shall define an epimorphism

$$\epsilon : \mathcal{E} \to C(K)_2.$$ 

Namely, if $x \in \mathcal{E}$, then there is a unique $\mathcal{O}_K$-ideal $A \subset K$ for which

$$x\mathcal{O}_K = A^2.$$ 

Set $\epsilon(x) = \text{cl}(A) \in C(K)_2$. This is an epimorphism for if $A$ is an $\mathcal{O}_K$-ideal for which $\text{cl}(A)^2 = \text{cl}(A^2) = 1 \in C(K)$, then by definition $x\mathcal{O}_K = A^2$ for some $x \in K^*$. Clearly $x \in \mathcal{E}$ with $\epsilon(x) = \text{cl}(A)$.

Now, $K^*/2 \subset \mathcal{E}$, but $\epsilon$ is trivial on $K^*/2$. That is, if $z^2 = x \in \mathcal{E}$, then $x\mathcal{O}_K = z^2\mathcal{O}_K = (z\mathcal{O}_K)^2$ so that $\epsilon(x) = \text{cl}(z\mathcal{O}_K) = 1 \in C(K)$. Then, there is an induced epimorphism, also denoted

$$\epsilon : E \to C(K)_2.$$ 

We shall now see that $\ker(\epsilon) \subset E$ is exactly $\mathcal{O}_K^*/\mathcal{O}_K^{*2} \subset E$.

Proposition 2.19. We have: $\ker(\epsilon) = \mathcal{O}_K^*/\mathcal{O}_K^{*2}$.

Proof. Suppose for $x \in \mathcal{E}$ that $x\mathcal{O}_K = a^2$ and $A$ is principal, that is $x \in \ker(\epsilon)$. Thus, $z\mathcal{O}_K = A$, for some $z \in K^*$. Hence $x\mathcal{O}_K = z^2\mathcal{O}_K$, therefore $x = uz^2$ for some $u \in \mathcal{O}_K^*$. In $E = \mathcal{E}/K^*/2$, we have $x = u$, hence $x \in \mathcal{O}_K^*/\mathcal{O}_K^{*2}$. It is trivial to see that $\mathcal{O}_K^*/\mathcal{O}_K^{*2} \subset \ker(\epsilon) \subset E$, for if $x = vw^2 \in \mathcal{O}_K^*/\mathcal{O}_K^{*2}$, then $\epsilon(x) = \epsilon(vw^2) = 1 \in C(K)$. \hfill $\Box$

Lemma 2.20. In $K^*/2$ the subgroup $E$ is a finite elementary abelian 2-group of 2-rank:

$$2\text{-rk } E = n + 2\text{-rk } C(K) = 2\text{-rk } \mathcal{O}_K^*/\mathcal{O}_K^{*2} + 2\text{-rk } C(K)_2.$$
Proof. Recall the short exact sequence:

\[ 1 \to \mathcal{O}_K^*/\mathcal{O}_K^{*2} \to E \to C(K)_2 \to 1. \]

Also, we have \( 2 \text{-rk } \mathcal{O}_K^*/\mathcal{O}_K^{*2} = n \) since \( K \) is totally real.

We can use the assumption that \( K \) contains units with independent signs to canonically embed \( C(K)_2 \) back into \( E \). Consider \( c \in C(K)_2 \) and represent \( c \) by an \( \mathcal{O}_K \)-ideal \( A \). Then \( A^2 \) is principal so \( x\mathcal{O}_K = A^2 \) for some \( x \in \mathcal{E} \). But \( \mathcal{O}_K^* \) contains units with independent signs, therefore for some \( u \in \mathcal{O}_K^* \), \( ux = y \) will be a totally positive generator for \( A^2 \). If \( y_1 \) is a second such totally positive generator then \( y_1y^{-1} = v \in \mathcal{O}_K^* \), with \( v \) totally positive. Thus, \( y_1 = y \) in \( E \) since every totally positive unit in \( \mathcal{O}_K^* \) is a square. We can continue to see that there is a homomorphism

\[ \eta : C(K)_2 \to E \]

with \( \epsilon \eta(c) = c, c \in C(K)_2 \). By taking \( E^+ \subset E \) to be the set of all totally positive square classes in \( E \) we find:

\[ E^+ \cong C(K)_2 \tag{2.1} \]

### 2.2 Quadratic Extensions

For \( 1 \neq \sigma \in K^*/K^{*2} \) we have the quadratic extension:

\[ F/K = K(\sqrt{\sigma})/K. \]

Then, \( k, 0 \leq k \leq n \), will denote the number of orderings of \( K \) with respect to which \( \sigma \) is positive. Thus \( k \) is the number of real infinite primes in \( K \) each of which splits into a conjugate pair of orderings of \( F \). Hence \( n - k \) is the number of real infinite primes in \( K \) which ramify in \( F \) into complex infinite primes. Thus:

\[ r_1(F) = 2k, \quad r_2(F) = n - k. \]
We denote by $S \subset \Omega_K$ the set of all infinite primes in $K$ together with all the finite primes in $K$ which ramify in $F/K$. Let us denote by $\mathcal{R}(F/K)$ the set of prime ideals $P \subset \mathcal{O}_K$ that ramify in $F/K$. Hence:

$$\#S = n + \#\mathcal{R}(F/K).$$

Let

$$\mathcal{E}_S = \{y \in K^* : \text{ord}_Py \equiv (0 \, \text{mod} \, 2) \text{ for all } P \notin S\} \subset K^*.$$ 

Thus, $y \in \mathcal{E}_S$ has even order at all unramified prime ideals $P \subset \mathcal{O}_K$. Obviously $K^{*2} \subset \mathcal{E}_S$ and $U_S \subset \mathcal{E}_S$, where $U_S \subset K^*$ is the subgroup of $S$-units. Now, every element of $K$ can be viewed as an element of $F$. In particular for $y \in \mathcal{E}_S$ we have:

1. If $P \subset \mathcal{O}_K$ and $P \in \Omega_K \cup S$, then for a prime ideal $\mathcal{P} \subset \mathcal{O}_F$ extending $P$ we have: $\text{ord}_{\mathcal{P}y} = \text{ord}_{P}y \equiv 0(\, \text{mod} \, 2)$.

2. If $P \subset \mathcal{O}_K$ and $P$ is ramified, then $p\mathcal{O}_K = \mathcal{P}^2$ and: $\text{ord}_{\mathcal{P}y} = 2\text{ord}_{P}y \equiv (0 \, \text{mod} \, 2)$.

Thus, if $y \in \mathcal{E}_S$, then $y\mathcal{O}_F = A^2$ for a unique $\mathcal{O}_F$-ideal $A$. Note that $\text{cl}(A) \in C(F)_2$. Then we have an homomorphism

$$H : \mathcal{E}_S \to C(F)_2.$$ 

If $y = z^2 \in \mathcal{E}_S$ we have $z^2\mathcal{O}_F = A^2$ or $(z\mathcal{O}_F)^2 = A^2$. Thus $A = z\mathcal{O}_F$ and $\text{cl}(A) = 1 \in C(F)_2$. Hence $H$ is trivial on $K^{*2} \subset \mathcal{E}_S$. Also, $H$ is trivial on $\mathcal{O}_K^* \subset \mathcal{E}_S$. Finally, recall that $F/K = F(\sqrt{\sigma})/K$, hence $\sigma \in \mathcal{E}_S$ and since $\sigma\mathcal{O}_F = (\sqrt{\sigma}\mathcal{O}_F)^2$ we see that $H(\sigma) = 1 \in C(F)_2$. We want to refine the group $\mathcal{E}_S$. First step is to note that $H$ is well defined on

$$E_S = \mathcal{E}_S/K^{*2} \subset K^*/K^{*2}.$$
Let $C_S(K)$ denote the quotient of the ideal class group $C(K)$ by the subgroup which is generated by the ideal classes of the ramified prime ideals $P \subset \mathcal{O}_K$. We need:

**Lemma 2.21.** There is a short exact sequence:

$$1 \to U_S/U_S^2 \to E_S \to C_S(K)_2 \to 1.$$ 

**Proof.** Consider $y \in \mathcal{E}_S$. Then there is an $\mathcal{O}_K$-ideal $B \subset \mathcal{O}_K$ such that $\text{ord}_P y = \text{ord}_P B^2 = 2\text{ord}_P B$ at all $P \subset \mathcal{O}_K$, $P \notin S$. While $B$ need not to be unique, it will define a unique $\text{cl}(B) \in C_S(K)_2$ with $\text{cl}(B^2) = 1$. If $y = x^2$, then $B$ may be taken to be $x\mathcal{O}_K$. Thus $\text{cl}(B) = 1 \in C_S(K)_2$. Hence we have an epimorphism

$$\epsilon : \mathcal{E}_S \to C_S(K)_2$$

which is trivial on $K^* \subset \mathcal{E}_S$.

Now suppose $\epsilon(y) = 1 \in C_S(K)_2$. Then, for $B \subset \mathcal{O}_K$ with $\text{ord}_P y = \text{ord}_P B^2$ at all $P \notin S$, there is an $x \in K^*$ for which $\text{ord}_P x = \text{ord}_P B$, at all $P \notin S$. Thus, $x^2y^{-1} \in U_S$ or $y \in \text{im}(U_S/U_S^2 \to E_S)$. 

Since $2\text{-rk } U_S/U_S^2 = \#S = \# \mathcal{R}(F/K) + n$ we conclude:

**Corollary 2.22.** The 2-rank of $E_S$ is $\# \mathcal{R}(F/K) + 2\text{-rk } C_S(K) + n$.

In the previous section we have introduced the homomorphism:

$$H : \mathcal{E}_S \to C(F)_2.$$ 

We have the following:

**Lemma 2.23.** If $y \in \mathcal{E}_S$, then $y \in \ker(H)$ if and only if there are $v \in \mathcal{O}_F^*$ and $x \in F^*$ for which $yv = x^2$. 

17
Proof. Assume \( y \in \ker(H) \). Then for \( y \mathcal{O}_F = A^2 \) we can write \( A = x \mathcal{O}_F \) for some \( x \in F^* \). Thus \( y \mathcal{O}_F = x^2 \mathcal{O}_F \) and hence for some \( v \in \mathcal{O}_F^* \) we have \( yv = x^2 \).

Conversely, if for some \( v \in \mathcal{O}_F^* \), and \( x \in F^* \) we have \( yv = x^2 \), then \( yv \mathcal{O}_F = y \mathcal{O}_F = x^2 \mathcal{O}_F \), hence \( A = x \mathcal{O}_F \) and \( H(y) = 1 \in C(F)_2 \).

Next we have:

**Lemma 2.24.** If \( v \in \mathcal{O}_F^* \), then there are elements \( y \in \mathcal{E}_S, x \in F^* \) for which \( yv = x^2 \) if and only if \( N(v) = v\bar{v} \in \mathcal{O}_K^2 \). That is, if and only if the norm of \( v \) is a square.

Proof. First, if \( yv = x^2 \), then \( N(yv) = y^2N(v) = (N(x))^2 \) and hence \( N(v) \) is a square. To see the converse, begin with the assumption \( v\bar{v} = 1 \). By Hilbert 90 we can write \( v = xx^{-1} \), for some \( x \in F^* \). Then \( xx^{-1} = v \), that is \( (x\bar{x})^{-1}v = (x^{-1})^2 \) and we can take \( y = (x\bar{x})^{-1} \in K^* \). Let us show that if \( yv = x^2 \), then \( y \in \mathcal{E}_S \).

We have \( y \mathcal{O}_F = yv \mathcal{O}_F = x^2 \mathcal{O}_F = (x \mathcal{O}_F)^2 \), whence \( \text{ord}_P y = \text{ord}_P x^2 = 2\text{ord}_P x \equiv 0 \pmod{2} \) for all \( P \notin S \). Thus \( y \in \mathcal{E}_S \). If \( N(v) = u^2, u \in \mathcal{O}_K^* \), then \( N(u^{-1}v) = 1 \).

So there is \( y \in \mathcal{E}_S, x \in K^* \) with \( yu^{-1}v = x^2 \). But \( yu^{-1} \in \mathcal{E}_S \).

We have a uniqueness problem. Suppose \( v \in \mathcal{O}_F^* \) with \( N(v) \) a square. If \( y, y_1 \in \mathcal{E}_S, x, x_1 \in F^* \) are such that \( yv = x^2 \) and \( y_1v = x_1^2 \), then \( y_1^{-1}y = (x_1x^{-1})^2 \).

Then, either \( y_1^{-1} \in K^{*2} \) or \( y_1^{-1} \) becomes a square in \( F^* \). But that means \( y_1^{-1} = (a + b\sqrt{\sigma})^2 \in K^* \) with \( a, b \in K \). Then \( a^2 + b^2\sigma + 2ab\sqrt{\sigma} \in K^* \) so \( ab = 0 \), whence \( a = 0 \) or \( b = 0 \). Thus, either

\[
y_1^{-1} = a^2 \in K^{*2}, \text{ or }
\]
\[
y_1^{-1} = b^2\sigma, \text{ hence } y_1^{-1} = (b\sigma)^2 \in K^{*2}.
\]

Let us conclude:

**Lemma 2.25.** If \( v\bar{v} \in \mathcal{O}_K^2 \) for \( v \in \mathcal{O}_F^* \) and \( yv = x^2, y_1v = x_1^2 \), where \( y, y_1 \in \mathcal{E}_S, x, x_1 \in F^* \), then either \( y_1^{-1} \in K^{*2} \) or \( \sigma y_1^{-1} \in K^{*2} \), but not both.
Let us introduce the subgroup $E^+_{S} \subset E_S$ consisting of those elements $y \in E_S$ which are positive in each ordering of $K$ with respect to which $\sigma$ itself is positive. Let us note that if $y \in E_S$, then there is a unit $u \in \mathcal{O}_K^*$ with $uy \in E^+_{S}$ since $K$ has units with independent signs. Since $H(u) = 1 \in C(F)_2$ we can restrict our attention to $E^+_{S}$. Now, $K^{*2} \subset E^+_{S}$ and, obviously, $\sigma \in E^+_{S}$. Then, let us name:

$$\overline{\mathcal{O}}_K^* = \mathcal{O}_K^* \cap E^+_{S}.$$ 

Still, $\mathcal{O}_K^{*2} \subset \overline{\mathcal{O}}_K^*$ and $2\text{-rk} \overline{\mathcal{O}}_K^*/\mathcal{O}_K^{*2} = n - k$. Let us now turn to:

$$E^+_{S} = E^+_{S}/K^{*2} \subset E_S.$$ 

We point out that $2\text{-rk} E_S = n + 2\text{-rk} C_S(K) + \# \mathcal{R}(F/K)$ and thus $2\text{-rk} E^+_{S} = n - k + 2\text{-rk} C_S(K) + \# \mathcal{R}(F/K)$. We still have $\overline{\mathcal{O}}_K^*/\mathcal{O}_K^{*2} \subset E^+_{S}$ and the square class of $\sigma \in E^+_{S}$. Yet, the induced homomorphism $H : E^+_{S} \to C(K)_2$ is trivial on the subgroup of $E^+_{S}$ generated by $\overline{\mathcal{O}}_K^*/\mathcal{O}_K^{*2}$ together with the square class of $\sigma$. Therefore we may as well factor out this subgroup resulting in a quotient group $\Pi$ together with an induced homomorphism

$$\chi : \Pi \to C(K)_2.$$ 

Now there are two possibilities for the infinite elementary abelian 2-group $\Pi$:

**Theorem 2.26.** If $\sigma \notin \mathcal{O}_K^*/\mathcal{O}_K^{*2}$, then

$$2\text{-rk} \Pi = \# \mathcal{R}(F/K) + 2\text{-rk} C_S(K) - 1.$$ 

However, if $\sigma \in \mathcal{O}_K^*/\mathcal{O}_K^{*2}$, then

$$2\text{-rk} \Pi = \# \mathcal{R}(F/K) + 2\text{-rk} C_S(K).$$ 

**Proof.** By the definition of $\Pi$ we have:

$$2\text{-rk} \Pi = 2\text{-rk} E^+_{S} - 2\text{-rk} \left( \overline{\mathcal{O}}_K^*/\mathcal{O}_K^{*2}; \sigma \right).$$
Now, 2-rk $E_s^+ = n - k + 2$-rk $C_s(K) + \#\mathcal{R}(F/K)$, while 2-rk $\left\langle \widetilde{O}_K^*/O_K^{r_2} ; \sigma \right\rangle = n - k$ if $\sigma \in O_K^*/O_K^{r_2}$, and 2-rk $\left\langle \widetilde{O}_K^*/O_K^{r_2} ; \sigma \right\rangle = n - k + 1$ if $\sigma \notin O_K^*/O_K^{r_2}$. Combining them, the lemma follows.

If $k = 0$, then $\sigma$ is totally negative and $O_F^+ = O_F$. However if $k > 0$, then each ordering of $K$ where $\sigma$ is positive splits into a conjugate pair of orderings of $F$. Then $F$ has $2k$ real orderings.

**Lemma 2.27.** If $v \in O_F^+$, then $N(v)$ is a square. If $v \in O_F^*$ with $N(v)$ a square, then $uv \in O_F^+$ for some $u \in O_K^*$.

**Proof.** If $v \in O_F^+$, then $\bar{v}v$ is positive at every ordering of $K$ where $\sigma$ is positive. Indeed, let $\eta : F \to \mathbb{R}$ be such that $\eta(\sigma) > 0$. Then $\eta_{1,2} : F \to \mathbb{R}$ extend $\eta$ and moreover $\eta(v\bar{v}) = \eta_1(v)\eta_2(v) > 0$ since $v \in O_F^+$. Now all norms from $F^*$ are positive with respect to all orderings of $K$ where $\sigma$ is negative. For, $\eta(N(a+b\sqrt{\sigma})) = \eta(a^2 - b^2\sigma) = [\eta(a)]^2 - \eta(\sigma)[\eta(b)]^2 > 0$ since $\eta(\sigma) < 0$.

So, for $v \in O_F^+$, $N(v) = \bar{v}v$ is totally positive in $O_K^*$ and therefore a square. This ends the first part of our lemma.

For the second part, let $v \in O_F^*$ be such that $N(v) = x^2$ is a square. Then:

$$0 < [\eta(x)]^2 = \eta(x^2) = \eta(N(v)) = \eta_1(v)\eta_2(v).$$

Hence, in each of a conjugate pair of orderings of $F$, $v$ must have the same sign. Since $O_K^*$ contains units with independent signs there is a unit $u \in O_K^*$ such that

$\eta(u) > 0$ if $\eta_1(v), \eta_2(v) > 0$ and

$\eta(u) < 0$ if $\eta_1(v), \eta_2(v) < 0$.

Then $\eta_i(uv) = \eta(u)\eta_i(v) > 0$, $i = 1, 2$. Therefore $uv \in O_F^+$. 

20
Thus, we shall consider only \( O_F^+/O_F^{*2} \). Now if \( v \in O_F^+ \) we have a \( y \in E_S \) with \( yv = x^2 \in F^* \). Since \( v \in O_F^+ \) we may conclude \( y \in E_S^+ \). Then \( y \) is unique up to multiplication by a \( z^2 \) or \( \sigma z^2 \). Recall that \( \Pi \) is the quotient of \( E^+ \) by the subgroup generated by \( K^*, \overline{O}_K^* \), and \( \sigma \). Hence we have a well defined homomorphism

\[ h : O_F^+ \to \Pi. \]

**Lemma 2.28.** The image of \( h \) is the kernel of \( \chi \).

**Proof.** Recall that:

\[ O_F^+ \xrightarrow{h} \Pi \xrightarrow{\chi} C(K)_2 \]

Let \( \text{cl}(y) \in \ker(\chi) \). Then \( yO_F = A^2 \) with \( A \) principal, so we can write \( A = xO_F \).

Hence \( yO_F = x^2O_F \) or \( yv = x^2 \) for some \( v \in O_F^+ \). Thus \( h(v) = \text{cl}(y) \) or \( \text{cl}(y) \in \text{im}(h) \).

On the other hand, if \( h(v) = \text{cl}(y) \in \text{im}(h) \), then \( yv = x^2 \). Thus \( yO_F = (xO_F)^2 \) and \( \chi(\text{cl}(y)) = \text{cl}(xO_F) = 1 \in C(K)_2 \). Therefore \( \text{cl}(y) \in \ker(\chi) \). \( \square \)

But we really need more information about \( h \). Surely \( O_F^{*2} \subset O_F^+ \) and \( h \) is trivial on \( O_F^{*2} \). Namely, if \( u^2 \in O_F^+ \) we can choose \( y \) to be 1. Thus we induce:

\[ h : O_F^+/O_F^{*2} \to \Pi. \]

**Lemma 2.29.** There is a natural homomorphism

\[ \overline{O}_K^*/O_K^{*2} \to O_F^+/O_F^{*2} \]

which is a monomorphism if \( \sigma \notin O_K^*/O_K^{*2} \) and whose kernel is cyclic of order 2 generated by the square class of \( \sigma \) if \( \sigma \in O_K^*/O_K^{*2} \).
Proof. Note that if \( u \in \widetilde{O}_K^* \), then \( u \in \mathcal{O}^+_F \) also, since only the real embeddings of \( K \) with respect to which \( \sigma \) is positive split into two real embeddings of \( F \). Thus we send the square class of \( \tau \in \widetilde{O}_K^*/\mathcal{O}_K^{*2} \) to the square class of \( \tau \in \mathcal{O}^+_F/\mathcal{O}_F^{*2} \).

Let \( \tau \in \widetilde{O}_K^*/\mathcal{O}_K^{*2} \) be such that \( \tau \) is in the kernel of our homomorphism. Then \( \tau \in \mathcal{O}_F^{*2} \) with \( \tau = (a + b\sqrt{\sigma})^2 = a^2 + \sigma b^2 + 2ab\sqrt{\sigma} \in \mathcal{O}_K^* \), so \( ab = 0 \). Thus: \( \tau = a^2 \) or \( \tau = b^2 \sigma \).

If \( \sigma \in \mathcal{O}_K^*/\mathcal{O}_K^{*2} \), then \( \tau = a^2 \) means \( \tau \) is trivial in \( \widetilde{O}_K^*/\mathcal{O}_K^{*2} \), and \( \tau = b^2 \sigma \) means \( \tau = \sigma \) in \( \widetilde{O}_K^*/\mathcal{O}_K^{*2} \). Hence, the kernel of our homomorphism is cyclic of order 2 generated by the square class of \( \sigma \).

If \( \sigma \notin \widetilde{O}_K^*/\mathcal{O}_K^{*2} \), then \( \tau = a^2 \) means \( \tau \) is trivial in \( \widetilde{O}_K^*/\mathcal{O}_K^{*2} \), and \( \tau = b^2 \sigma \) is impossible. Thus, in this case, our homomorphism is actually a monomorphism.

\( \square \)

Lemma 2.30. (i) If \( \sigma \notin \mathcal{O}_K^*/\mathcal{O}_K^{*2} \), then the sequence

\[ 1 \rightarrow \widetilde{O}_K^*/\mathcal{O}_K^{*2} \rightarrow \mathcal{O}_F^+/\mathcal{O}_F^{*2} \xrightarrow{h} \ker(\chi) \rightarrow 1 \]

is exact.

(i) If \( \sigma \in \mathcal{O}_K^*/\mathcal{O}_K^{*2} \), then the sequence

\[ 1 \rightarrow C_2 \rightarrow \widetilde{O}_K^*/\mathcal{O}_K^{*2} \rightarrow \mathcal{O}_F^+/\mathcal{O}_F^{*2} \xrightarrow{h} \ker(\chi) \rightarrow 1 \]

is exact.

Proof. Take \( v \in \mathcal{O}_F^+ \) and write \( yv = x^2 \). Suppose we could write \( y = uz^2 \sigma \) or \( y = uz^2 \), i.e. \( y \in \ker(h) \), for some \( u \in \widetilde{O}_K^* \), \( z \in K^* \).

If \( y = uz^2 \), then \( yv = uvz^2 = x^2 \), and hence \( uv = (x/z)^2 \in F^{*2} \). Thus \( v \in \mathcal{O}_F^+ \) lies in \( \ker(h) \), and in \( \mathcal{O}_F^*/\mathcal{O}_F^{*2} \), \( v \) lies in the image of the natural homomorphism 2.29.

If \( y = uz^2 \sigma \), then \( yv = uz^2(\sqrt{\sigma})^2v = x^2 \), and \( uv = (xz^{-1}/\sqrt{\sigma})^2 \in F^{*2} \). Again \( v \) lies in the image of the natural homomorphism 2.29.
On the other hand, if \( v \) lies in this image, then \( h(v) = 1 \in \Pi \).

Note that in our context, \( \text{Gal}(F/K) = C_2 \) acts as an automorphism of period 2 on \( \mathcal{O}_F^\times \), the group of units in \( F \). We define, then, the Artin-Tate cohomology groups

\[
\begin{align*}
H^0(C_2; \mathcal{O}_F^\times) & \quad \text{and} \quad H^1(C_2; \mathcal{O}_F^\times) .
\end{align*}
\]

First, by definition:

\[
H^0(C_2; \mathcal{O}_F^\times) = \mathcal{O}_K^\times / N(\mathcal{O}_F^\times) = \text{coker}(N).
\]

Thus each \( u \in \mathcal{O}_K^\times \) defines an element \( \text{cl}(u) \in H^0(C_2; \mathcal{O}_F^\times) \) which is trivial if and only if \( u = N(v) = v\bar{v} \) for some \( v \in \mathcal{O}_F^\times \).

To define \( H^1(C_2; \mathcal{O}_F^\times) \) we turn to \( \ker(N) \). Thus, \( v \in \mathcal{O}_F^\times \) defines a cohomology class \( \text{cl}(v) \in H^1(C_2; \mathcal{O}_F^\times) \) if and only if \( N(v) = 1 \). Then, \( \text{cl}(v) \) is trivial if and only if \( v = w\bar{w}^{-1} \) for some \( w \in \mathcal{O}_F^\times \). Both \( H^0(C_2; \mathcal{O}_F^\times) \) and \( H^1(C_2; \mathcal{O}_F^\times) \) are elementary abelian 2-groups.

Note that \(-1 \in \mathcal{O}_F^\times\) always defines a cohomology class \( \text{cl}(-1) \in H^1(C_2; \mathcal{O}_F^\times) \). This cohomology class is trivial if and only if there is a unit \( w \in \mathcal{O}_F^\times \) for which \( w\bar{w}^{-1} = -1 \), or \( \bar{w} = -w \). When we might find such a skew unit? We can write \( w = \alpha + \beta\sqrt{\sigma} \in \mathcal{O}_F^\times \) for unique \( \alpha, \beta \in K^\times \). Since \( \bar{w} = -w \) we have \( \alpha = 0 \). Thus, \( \beta\sqrt{\sigma} \in \mathcal{O}_F^\times \). Then \( N(\beta\sqrt{\sigma}) = -\beta^2\sigma \in \mathcal{O}_K^\times \). Hence a square class \( \sigma \in \mathcal{O}_K^\times / \mathcal{O}_K^{\times 2} \). We have proved:

**Lemma 2.31.** In \( H^1(C_2; \mathcal{O}_F^\times) \) the \( \text{cl}(-1) \) is trivial if and only of \( \sigma \in \mathcal{O}_K^\times / \mathcal{O}_K^{\times 2} \).

In general we use \( H^1(C_2; \mathcal{O}_F^\times)/\text{cl}(-1) \) to denote the quotient of \( H^1(C_2; \mathcal{O}_F^\times) \) by the subgroup of at most order 2 which is generated by \( \text{cl}(-1) \). Our task is to define a natural epimorphism

\[
\rho : \mathcal{O}_F^\times / \mathcal{O}_F^{\times 2} \to H^1(C_2; \mathcal{O}_F^\times)/\text{cl}(-1) \to 1
\]
whose kernel is the image of the natural homomorphism 2.29.

We begin with \( v \in \mathcal{O}_F^+ \). Then \( N(v) = u^2 \), \( u \in \mathcal{O}_K^* \), and \( N(u^{-1}v) = u^{-2}N(v) = 1 \). Hence, \( u^{-1}v \) defines \( \text{cl}(u^{-1}v) \in H^1(C_2; \mathcal{O}_F^+) \). Carefully note that \((-u)^2 = N(v)\) also, and \( \text{cl}(u^{-1}v) = \text{cl}(1)\text{cl}(u^{-1}v) \). Thus we obtain a well defined homomorphism:

\[
\eta: \mathcal{O}_F^+ \to H^1(C_2; \mathcal{O}_F^+)/\text{cl}(1).
\]

This is an epimorphism. For, if \( v_1 \in \mathcal{O}_F^* \) with \( N(v_1) = 1 \), then by Lemma 2.27 we can choose a unit \( u \in \mathcal{O}_K^* \) so that \( uv_1 \in \mathcal{O}_F^+ \). Then \( N(uv_1) = u^2 \) and \( u^{-1}uv_1 = v_1 \) so \( \eta(uv_1) = \text{cl}(v_1) \in H^1(C_2; \mathcal{O}_F^+)/\text{cl}(1) \).

Let us check that \( \eta \) is trivial on \( \mathcal{O}_F^2 \subset \mathcal{O}_F^+ \). For \( v^2 \in \mathcal{O}_F^2 \) we have \( N(v^2) = [N(v)]^2 \).

Taking \( u = N(v) \) we get \( u^{-1}v^2 = v^{-1}v^{-1}v^2 = v\bar{v}^{-1} \), hence \( \eta(v^2) \) is trivial. Thus we arrive at the epimorphism: \( \rho: \mathcal{O}_F^+/\mathcal{O}_F^2 \to H^1(C_2; \mathcal{O}_F^+)/\text{cl}(1) \).

Let us next assume for \( v \in \mathcal{O}_F^+ \) that \( \eta(v) \) is trivial in \( H^1(C_2; \mathcal{O}_F^+)/\text{cl}(1) \), i.e. \( v \in \ker(\eta) \). Since \( N(v) = u^2 \), for some \( u \in \mathcal{O}_K^* \) we get \( \text{cl}(u^{-1}v) = 1 \in H^1(C_2; \mathcal{O}_F^*) \).

Thus \( w\bar{w}^{-1} = u^{-1}v \) for some \( w \in \mathcal{O}_F^+ \). We write: \( w\bar{w}w^{-2} = u^{-1}v \) or \( uw\bar{w} = vw^2 \).

Then, \( uw\bar{w} \in \mathcal{O}_K^* \) but since \( vw^2 \in \mathcal{O}_F^+ \) it follows that \( uw\bar{w} \in \mathcal{O}_K^* \). Hence, the square class of \( v \in \mathcal{O}_F^+/\mathcal{O}_F^2 \) lies in the image of the natural homomorphism 2.29.

Conversely, if \( v \in \mathcal{O}_F^+ \) assume \( v = uw^2 \) for some \( u \in \mathcal{O}_K^*, w \in \mathcal{O}_F^* \). Then, \( N(v) = u^2 [N(w)]^2 \). Thus we consider the class of

\[
u^{-1}w^{-1}\bar{w}^{-1}v = u^{-1}w^{-1}\bar{w}^{-1}uw^2 = w\bar{w}^{-1}.
\]

Hence, when \( v \in \mathcal{O}_F^+/\mathcal{O}_F^2 \) lies in the image of the natural homomorphism 2.29 we find \( \eta(v) = 1 \in H^1(C_2; \mathcal{O}_F^*) \). Using, in addition, Lemma 2.31 and Lemma 2.30, we obtain the following:

**Theorem 2.32.** We have:

\[
\ker(\chi) \cong H^1(C_2; \mathcal{O}_F^+)/\text{cl}(1).
\]
Thus, if $\sigma \notin O_K^*/O_{K^2}^*$, then:

$$1 + 2 \cdot \text{rk} \ker(\chi) = 2 \cdot \text{rk} H^1(C_2; O_F^*),$$

while if $\sigma \in O_K^*/O_{K^2}^*$, then:

$$2 \cdot \text{rk} \ker(\chi) = 2 \cdot \text{rk} H^1(C_2; O_F^*).$$

From [4], Proposition 5.2, we know:

$$1 + 2 \cdot \text{rk} H^0(C_2; O_F^*) = n - k + 2 \cdot \text{rk} H^1(C_2; O_F^*). \quad (2.2)$$

Let us combine this formula with Theorem 2.32 and obtain:

**Corollary 2.33.** (i) If $\sigma \notin O_K^*/O_{K^2}^*$, then:

$$2 \cdot \text{rk} H^0(C_2; O_F^*) = n - k + 2 \cdot \text{rk} \ker(\chi).$$

(ii) If $\sigma \in O_K^*/O_{K^2}^*$, then:

$$1 + 2 \cdot \text{rk} H^0(C_2; O_F^*) = n - k + 2 \cdot \text{rk} \ker(\chi).$$

Now we are able to prove the following:

**Lemma 2.34.** (i) If $\sigma \notin O_K^*/O_{K^2}^*$, then:

$$0 \leq 2 \cdot \text{rk} \ker(\chi) \leq k.$$

(ii) If $\sigma \in O_K^*/O_{K^2}^*$, then:

$$1 \leq 2 \cdot \text{rk} \ker(\chi) \leq k + 1.$$

**Proof.** Since $2 \cdot \text{rk} O_K^*/O_{K^2}^* = n$, and $O_{K^2}^* \subset \text{im}(N)$ it follows that $H^0(C_2; O_F^*) = \text{coker}(N)$ must have $2 \cdot \text{rk} H^0(C_2; O_F^*) \leq n$. If $\sigma \notin O_K^*/O_{K^2}^*$, then by Corollary 2.33(i) we have $2 \cdot \text{rk} H^0(C_2; O_F^*) = n - k + 2 \cdot \text{rk} \ker(\chi) \leq n$. Therefore $0 \leq 2 \cdot \text{rk} \ker(\chi) \leq k$. 

25
Next, recall formula 2.2. Then, $2\text{-rk} H^0(C_2; \mathcal{O}^*_K) \geq n - k$. Namely, if a unit $u \in \mathcal{O}^*_K$ is negative with respect to at least one ordering of $K$ where $\sigma$ is also negative, then $u$ cannot be a norm from $F/K$ and there are $n - k$ orderings of $K$ at which $\sigma$ is negative. It follows that $2\text{-rk} H^1(C_2; \mathcal{O}^*_K) \geq 1$ in all cases. But if $\sigma \in \mathcal{O}^*_K/\mathcal{O}^*_K^2$ it must follow that, by Theorem 2.32, $2\text{-rk} \ker(\chi) \geq 1$. Then by Corollary 2.33(ii) we have $1 \leq 2\text{-rk} \ker(\chi) \leq k + 1$. \hfill \Box

There is a natural homomorphism:

$$i_* : C(K) \rightarrow C(F).$$

This assigns to the ideal class of a fractional $\mathcal{O}_K$-ideal $A \subset \mathcal{O}_K$ the ideal class in $C(F)$ of the fractional $\mathcal{O}_F$-ideal $A\mathcal{O}_F \subset F$. We may restrict this to:

$$i_* : C(K)_2 \rightarrow C(F)_2,$$

We wish to relate the homomorphism $i_*$ to the homomorphism $\chi : \Pi \rightarrow C(F)_2$.

First we return to the subgroup of square classes $E^+ \subset \mathcal{K}^*/\mathcal{K}^*_2$, defined by $z \in E^+$ if and only if $z$ is totally positive and $\text{ord}_P z \equiv 0 \text{ mod } 2$ at every prime ideal $P \subset \mathcal{O}_K$. We already noted the natural isomorphism 2.1

$$C(K)_2 \cong E^+.$$ 

Recall that if the $\mathcal{O}_K$-ideal $A$ represents $\text{cl}(A) \in C(K)_2$, then to $\text{cl}(A)$ we assign the square class $z \in E^+$ of the totally positive generator of $A^2$.

**Lemma 2.35.** If $\sigma \in \mathcal{K}^*/\mathcal{K}^*_2$, then $K(\sqrt{\sigma})/K$ is unramified if and only if $\sigma \in E^+$. 

**Proof.** First, it is clear that if $K(\sqrt{\sigma})/K$ is unramified, then $\sigma \in E^+ \subset \mathcal{K}^*/\mathcal{K}^*_2$. Second, from Class Field Theory we know that the maximum number of unramified independent quadratic extensions of $K$ is equal to $2\text{-rk} C(K) = 2\text{-rk} C(K)_2 = 2\text{-rk} E^+$. \hfill \Box
Now we examine $\text{ker}(i_*) \subset C(K)_2$. First assume that $K(\sqrt{\sigma})/K$ has at least one ramified prime. Then by Lemma 2.35 $\sigma \not\in E^+$. We know that $O_K^*/O_K'^2 \cap E^+$ is trivial. Thus $E^+ \subset E_S$ and the quotient onto $\Pi$ gives us a monomorphism $I_* : C(K)_2 \to \Pi$. Furthermore, the composition:

$$C(K)_2 \xrightarrow{I_*} \Pi \xrightarrow{\chi} C(F)_2$$

is exactly $i_* : C(K)_2 \to C(F)_2$. Thus $\text{ker}(i_*) \subset \text{ker}(\chi)$.

If $K(\sqrt{\sigma})/K$ is unramified the situation is quite different! In this case, $S \subset \Omega_K$ consists only of the real infinite primes. Thus $C_S(K) = C(K)$ and $E_S = E$. But we must be careful! Since now $\sigma \in E^+$, we see that $I_*$ will have kernel cyclic of order 2, but it will be onto. Therefore in the ramified case we have:

$$\xymatrix{1 \ar[r] & C_2 \ar[r] & (K)_2 \ar[r]^{I_*} & \Pi \ar[r] & 1}$$

and:

$$2 \cdot \text{rk ker}(i_*) = 1 + 2 \cdot \text{rk ker}(\chi) \quad (2.3)$$

Although $F$ may not be totally real, we may still ask if it contains units with independent signs. If $K(\sqrt{\sigma})/K$ is a CM-extension (i.e. $\sigma$ is totally negative) then $O_F^+ = O_F^*$ by default.

**Corollary 2.36.** If $\sigma \not\in O_K^*/O_K'^2$ then the following are equivalent:

1. $O_F^*$ contains units with independent signs.
2. $\text{ker}(\chi)$ is trivial.
3. $2 \cdot \text{rk} H^0(C_2; O_F^*) = n - k$.
4. Every unit of $O_K^*$ which is positive at every ordering of $K$ with respect to which $\sigma$ is negative, is the norm of a unit in $O_F^*$.
5. $H^1(C_2; O_F^*)$ is cyclic of order 2 (generated by $\text{cl}(-1)$).
Proof. Note that $2 \iff 3$ by 2.33 which says:

$$2 \text{-rk } H^0(C_2; \mathcal{O}^*_K) = n - k + 2 \text{-rk } \ker(\chi).$$

Also, $3 \iff 5$ by 2.32 which says:

$$1 + 2 \text{-rk } H^0(C_2; \mathcal{O}^*_F) = n - k + 2 \text{-rk } H^1(C_2; \mathcal{O}^*_F).$$

Let us prove that $4 \Rightarrow 1$. Let $\eta_1, \eta_2, \ldots, \eta_k : K \to \mathbb{R}$ be the orderings of $K$ with respect to which $\sigma$ is positive. They extend (split) to $\eta_{1,2}^1, \ldots, \eta_{k,2}^1 : F \to \mathbb{R}$. Choose one of the real embeddings of $F$, say $\eta_1^1$. Since $K$ has units with independent signs we can find $v \in \mathcal{O}^*_K$ such that:

- $\eta_1(v) < 0$,
- $\eta_i(v) > 0$ if $i = 2, \ldots, k$,
- $\eta_j(v) > 0$ if $j = k + 1, \ldots, n$.

So $v$ is a unit which is positive whenever $\sigma$ is negative. Hence there exists $V \in \mathcal{O}^*_F$ so that $v = V\bar{V}$. Then:

- $\eta_1(v) = \eta_1^1(V)\eta_1^2(V) < 0$,
- $\eta_i(v) = \eta_i^1(V)\eta_i^2(V) > 0$ if $i = 2, \ldots, k$.

Suppose that $\eta_1^1(V) < 0$, otherwise we can replace $V$ with $-V$. Now choose $u \in \mathcal{O}^*_K$ such that:

- $\eta_1(u) > 0$,
- if $\eta_i^1(V), \eta_i^2(V) > 0$, then $\eta_i(u) > 0$,
- if $\eta_i^1(V), \eta_i^2(V) < 0$, then $\eta_i(u) < 0$, where $i = 2, \ldots, k$.

Then:

- $\eta_1^1(uV) = \eta_1(u)\eta_1^1(V) < 0$,
- $\eta_i^2(uV) = \eta_1(u)\eta_i^2(V) > 0$, and
- $\eta_i^s(uV) = \eta_i(u)\eta_i^s(V) > 0$ for $i = 2, \ldots, k$, $s = 1, 2$.

Therefore, $F$ has units with independent signs.
Now we will show that $1 \Rightarrow 4$. Since $F$ has units with independent signs, there is a unit $V \in \mathcal{O}_F^*$ so that: $\eta_1^1(V)\eta_1^2(V) < 0$ and $\eta_i^1(V)\eta_i^2(V) > 0$ for $i = 2, \ldots, k$. Let $v = V\bar{V} \in \mathcal{O}_K^*$. Then:

\[
\eta_1(v) = \eta_1^1(V)\eta_1^2(V) < 0,
\]
\[
\eta_i(v) = \eta_i^1(V)\eta_i^2(V) > 0 \text{ for } i = 2, \ldots, k,
\]
\[
\eta_j(v) = \eta_j(V\bar{V}) = \eta_j(a^2 - \sigma b^2) = [\eta_j(a)]^2 - \eta_j(\sigma)[\eta_j(b)]^2 > 0 \text{ for } j = k+1, \ldots, n.
\]

Hence $K$ has units with independent signs. Actually we have shown that $\mathcal{O}_K^*$ contains units (which are positive whenever $\sigma$ is negative) with independent signs that are norms from $\mathcal{O}_F^*$. Hence any unit (positive whenever $\sigma$ is negative) in $\mathcal{O}_K^*$ can be written as the product of a totally positive unit in $\mathcal{O}_K^*$ with a unit (positive whenever $\sigma$ is negative) that is a norm from $\mathcal{O}_F^*$. Since $K$ is totally real, any totally positive unit is a square, hence a norm from $\mathcal{O}_F^*$.

Finally, $3 \Leftrightarrow 4$ is clear by the definition of $H^0(C_2; \mathcal{O}_F^*)$.

$\square$

If $\sigma \in \mathcal{O}_K^*/\mathcal{O}_K^{*2}$, then we can prove similarly the following:

**Corollary 2.37.** If $\sigma \in \mathcal{O}_K^*/\mathcal{O}_K^{*2}$ then the following are equivalent:

1. $\mathcal{O}_F^*$ contains units with independent signs.
2. $\ker(\chi)$ is cyclic of order 2.
3. $2\cdot \text{rk } H^0(C_2; \mathcal{O}_F^*) = n - k$.
4. Every unit of $\mathcal{O}_K^*$ which is positive at every ordering of $K$ with respect to which $\sigma$ is negative, is the norm of a unit in $\mathcal{O}_F^*$.
5. $H^1(C_2; \mathcal{O}_F^*)$ is cyclic of order 2.

If $\mathcal{A}(K)$, $\mathcal{A}(F)$ are the abelian groups of all fractional $\mathcal{O}_K$-, respectively $\mathcal{O}_F$-ideals, we can define a norm of ideals homomorphism

\[ N : \mathcal{A}(F) \to \mathcal{A}(K). \]
It is enough to consider prime ideals. If $\mathcal{P} \subset \mathcal{O}_F$ is a prime ideal in $\mathcal{O}_F$, then $\mathcal{P}|P$ for a unique prime ideal $P \subset \mathcal{O}_K$. If $P$ is either split or ramified, then $N(P) = P$, while if $P$ is inert, then $N(P) = P^2$. We define $N$ so that for $x \in F$ we have $N(x\mathcal{O}_F) = N(x)\mathcal{O}_K$. In any case there is an induced homomorphism of ideal class groups

$$N: \mathcal{C}(F) \to \mathcal{C}(K).$$

Let us prove the following:

**Proposition 2.38.** The image of $\chi$ lies in the kernel of $N$.

**Proof.** Let $y \in K^*$ be an element for which $\text{ord}_P y \equiv 0 \pmod{2}$ at all unramified prime ideals $P \subset \mathcal{O}_K$. Then we write $y\mathcal{O}_F = A^2$. We have the following cases:

(i) If $P$ is inert, then:

$$\text{ord}_P A = \frac{1}{2}\text{ord}_P A^2 = \frac{1}{2}\text{ord}_P y\mathcal{O}_F = \frac{1}{2}\text{ord}_P y,$$

hence $N(P)^{\text{ord}_P A} = P^{\text{ord}_P y}$.

(ii) If $P$ is ramified, then $\text{ord}_P A = \text{ord}_P y$, and hence $N(P)^{\text{ord}_P A} = P^{\text{ord}_P y}$.

(iii) If $P$ splits, then $2\text{ord}_P A = \text{ord}_P y$.

Therefore:

$$N(A) = N\left(\prod_{\mathcal{P}|A} \mathcal{P}^{\text{ord}_P A}\right) = \prod_{\mathcal{P}|A} N(\mathcal{P})^{\text{ord}_P A} = \prod_{\mathcal{P}|y\mathcal{O}_K} P^{\text{ord}_P y} = y\mathcal{O}_K.$$  

Since $\chi(y) = \text{cl}(A) \in C(F)_2$, we see that:

$$N(\chi(y)) = N(\text{cl}(A)) = \text{cl}(N(A)) = \text{cl}(y\mathcal{O}_K) = 1 \in C(K),$$

hence $\text{im}(\chi) \subseteq \ker(N)$.

Referring to the exact hexagon 1.18, let us prove the following:

**Theorem 2.39.** If the class number $h(K)$ is odd, then

$$2\text{-rk coker}(\chi) = 2\text{-rk ker}(i_0).$$
Proof. Since $h(K)$ is odd at least one finite prime ramifies and the natural homomorphism $i_* : C(K) \to C(F)$ has trivial kernel. Hence, by Proposition 7.1 [4],

$j_1 : R^0(F/K) \to H^1(C_2; C(F))$ is an epimorphism. Furthermore, $H^1(C_2; C(F)) \cong C(F)/C(F)^2$ and thus $2\text{-rk } C(F)^2 = 2\text{-rk } C(F)/C(F)^2 = 2\text{-rk } H^1(C_2; C(F))$. We also now (see Proposition 4.2 [4]) that $2\text{-rk } R^0(F/K) = n - k + \# R(F/K) - 1$.

Thus from the exact hexagon we have:

$$2\text{-rk } R^0(F/K) = 2\text{-rk } \ker(j_1) + 2\text{-rk } \text{im}(j_1)$$

$$= 2\text{-rk } \text{im}(i_0) + 2\text{-rk } H^1(C_2; C(F))$$

$$= 2\text{-rk } H^0(C_2; \mathcal{O}_F^*) - 2\text{-rk } \ker(i_0) + 2\text{-rk } H^1(C_2; C(F))$$

Therefore:

$$n - k + \# R(F/K) - 1 - 2\text{-rk } H^0(C_2; \mathcal{O}_F^*) + 2\text{-rk } \ker(i_0) = 2\text{-rk } H^1(C_2; C(F)).$$

Now, if $\sigma \notin \mathcal{O}_K^*/\mathcal{O}_K^{*2}$ then we know by Corollary 2.33 that $2\text{-rk } H^0(C_2; \mathcal{O}_F^*) = n - k + 2\text{-rk } \ker(\chi)$. Therefore $2\text{-rk } H^1(C_2; C(F)) = \# R(F/K) - 2\text{-rk } \ker(\chi) - 1 + 2\text{-rk } \ker(i_0)$. But we also know that in this case, see Lemma 2.26, that $2\text{-rk } \Pi = \# R(F/K) - 1$. Hence we have $\# R(F/K) - 2\text{-rk } \ker(\chi) - 1 = 2\text{-rk } \text{im}(\chi)$. Thus $2\text{-rk } \ker(\chi) = 2\text{-rk } \ker(i_0)$.

Now we must consider the case $\sigma \in \mathcal{O}_K^*/\mathcal{O}_K^{*2}$. Again, by Corollary 2.33 we have $1 + 2\text{-rk } H^0(C_2; \mathcal{O}_F^*) = n - k + 2\text{-rk } \ker(\chi)$. Still $2\text{-rk } R^0(F/K) = n - k + \# R(F/K) - 1$. Referring to the exact hexagon we obtain:

$$2\text{-rk } H^1(C_2; C(F)) = \# R(F/K) - 2\text{-rk } \ker(\chi) + 2\text{-rk } \ker(i_0).$$

This time Lemma 2.26 gives us that $2\text{-rk } \Pi = \# R(F/K)$. Thus $2\text{-rk } \text{im}(\chi) = \# R(F/K) - 2\text{-rk } \ker(\chi)$ and again we obtain:

$$2\text{-rk } \text{coker}(\chi) = 2\text{-rk } \ker(i_0).$$

\[\square\]
We have the following:

**Corollary 2.40.** If \( h(K) \) is odd, then the homomorphism \( \chi \) is an epimorphism if and only if the homomorphism \( i_0 \) is a monomorphism.

We can restate Corollary 2.40 as follows:

**Remark 2.41.** If \( h(K) \) is odd, then the homomorphism \( \chi \) is an epimorphism if and only if each unit in \( O_K^* \) which is a norm from \( F/K \) is also the norm of a unit in \( O_F^* \).

We know that possibly \( 2\text{rk } H^0(C_2; O_F^*) = n - k \). But that means that a unit in \( O_K^* \) fails to be the norm of a unit in \( O_F^* \) if and only if it is negative with respect to at least one ordering of \( K \) with respect to which \( \sigma \) is also negative. However, such a unit in \( O_K^* \) cannot even be a field norm from \( F/K \). Therefore:

**Proposition 2.42.** If \( h(K) \) is odd and \( 2\text{rk } H^0(C_2; O_F^*) = n - k \), then \( i_0 \) is a monomorphism.

Recall, see Corollary 2.36, that if \( \sigma \notin O_K^*/O_K^2 \), then \( \ker(\chi) \) is trivial if and only if \( 2\text{rk } H^0(C_2; O_F^*) = n - k \) if and only if \( O_F^* \) contains units with independent signs. Also, if \( \sigma \in O_K^*/O_K^2 \), then \( 2\text{rk } H^0(C_2; O_F^*) = n - k \) if and only if \( 2\text{rk } \ker(\chi) = 1 \) if and only if \( O_F^* \) contains units with independent signs (by Corollary 2.37). Thus we obtain:

**Corollary 2.43.** If \( h(K) \equiv 1 \pmod{2} \) and \( O_F^* \) contains units with independent signs, then:

\[(i) \ 2\text{rk } C(F)_2 = \#R(F/K) - 1,\]

\[(ii) \ If \ \sigma \notin O_K^*/O_K^2, \ then \ \Pi \cong C(F)_2,\]

\[(iii) \ If \ \sigma \in O_K^*/O_K^2, \ then \ \ker(\chi) \ is \ cyclic \ of \ order \ 2.\]
Since $K$ has units with independent signs, we see that $h(K) = h^+(K) \equiv 1 \pmod{2}$. Hence $C(F) = H^0(C_2; C(F))$. Thus, the homomorphism $d_0$ can be regarded as $d_0 : C(F) \rightarrow H^0(C_2; \mathcal{O}_F^*)$. We showed, see Theorem 2.32, that $\text{ker}(\chi) \cong H^1(C_2; \mathcal{O}_F^*) / \text{cl}(-1)$. Then we can see that there is an epimorphism

$$\rho : H^1(C_2; \mathcal{O}_F^*) \rightarrow \text{ker}(\chi)$$

and $\text{ker}(\rho)$ is the cyclic subgroup of $H^1(C_2; \mathcal{O}_F^*)$ generated by $\text{cl}(-1)$.

**Theorem 2.44.** If $K$ is a totally real number field with $h^+(K) \equiv 1 \pmod{2}$ then for $F/K = K(\sqrt{\sigma})/K$ there is an associated exact sequence:

$$1 \rightarrow \text{cl}(-1) \rightarrow H^1(C_2; \mathcal{O}_F^*) \xrightarrow{\rho} \Pi \xrightarrow{\chi} C(F)_2 \xrightarrow{d_0} H^0(C_2; \mathcal{O}_F^*) \xrightarrow{i_0} R^0(F/K) \rightarrow C(F)/C(F)_2 \rightarrow 1.$$ 

**Proof.** From the exact hexagon we know $\text{im}(d_0) = \text{ker}(i_0)$. Also Theorem 2.39 gives: $2\text{-rk} \text{im}(\chi) + 2\text{-rk} \text{ker}(i_0) = 2\text{-rk} C(F)_2 = 2\text{-rk} \text{im}(\chi)2\text{-rk} \text{im}(d_0)$ and also: $2\text{-rk} C(F)_2 = 2\text{-rk} \text{im}(d_0) + 2\text{-rk} \text{ker}(d_0)$, hence $2\text{-rk} \text{im}(\chi) = 2\text{-rk} \text{ker}(d_0)$, whence $\text{im}(\chi) \cong \text{ker}(d_0)$, since both are elementary 2-abelian groups. Thus to show that $\text{im}(\chi) = \text{ker}(d_0)$ we only need to verify that $\text{im}(\chi) \subseteq \text{ker}(d_0)$. An element in $\text{im}(\chi)$ is represented by a fractional $\mathcal{O}_F$-ideal $A \subset F$ for which $A = \widetilde{A}$. Thus $\widetilde{A} = xA$, $(x = 1)$, so $x\widetilde{x} = 1$ and thus: $d_0(\text{cl}(A)) = \text{cl}(x\widetilde{x}) = \text{cl}(1) \in H^0(C_2; \mathcal{O}_F^*)$. Therefore, $\text{im}(\chi) \subseteq \text{ker}(d_0)$ and we are done. 

The goal is to express the 2-rank of the class group $C(F)$ in terms of the homomorphism:

$$\chi : \Pi \rightarrow C(F)_2.$$ 

We recall that $\#\mathcal{R}(F/K) \geq 1$ and (see [4] 4.2)

$$2\text{-rk} R^0(F/K) = n - k + \#\mathcal{R}(F/K) - 1.$$ 

33
Also we have $H^1(C_2; C(F)) \cong C(F)/C(F)_2$, while $j_1 : R^0(F/K) \rightarrow H^1(C_2; C(F))$ is onto. Thus from the exact hexagon we write:

$$2\text{-rk} \text{im}(i_0) = 2\text{-rk} H^0(C_2; \mathcal{O}_F^*) - 2\text{-rk} \text{ker}(i_0).$$

Hence:

$$2\text{-rk} \frac{C(F)}{C(F)_2} = 2\text{-rk} H^1(C_2; C(F)) = 2\text{-rk} \text{im}(j_1)$$

$$= 2\text{-rk} R^0(F/K) - 2\text{-rk} \text{ker}(j_1)$$

$$= 2\text{-rk} R^0(F/K) - 2\text{-rk} \text{im}(i_0)$$

$$= n - k + \# \mathcal{R}(F/K) - 1 - 2\text{-rk} H^0(C_2; \mathcal{O}_F^*) + 2\text{-rk} \text{ker}(i_0).$$

We already showed (see 2.39) that:

$$2\text{-rk} \text{coker}(\chi) = 2\text{-rk} \text{ker}(i_0),$$

while (see 2.33):

$$2\text{-rk} H^0(C_2; \mathcal{O}_F^*) = n - k + 2\text{-rk} \ker(\chi) \text{ if } \sigma \notin \mathcal{O}_K^*/\mathcal{O}_K^{*2}$$

and

$$1 + 2\text{-rk} H^0(C_2; \mathcal{O}_F^*) = n - k + 2\text{-rk} \ker(\chi) \text{ if } \sigma \in \mathcal{O}_K^*/\mathcal{O}_K^{*2}.$$ 

Hence:

$$2\text{-rk} C(F) = \# \mathcal{R}(F/K) - 1 - 2\text{-rk} \ker(\chi) + 2\text{-rk} \text{coker}(\chi), \text{ if } \sigma \notin \mathcal{O}_K^*/\mathcal{O}_K^{*2}$$

and

$$2\text{-rk} C(F) = \# \mathcal{R}(F/K) - 2\text{-rk} \ker(\chi) + 2\text{-rk} \text{coker}(\chi), \text{ if } \sigma \in \mathcal{O}_K^*/\mathcal{O}_K^{*2}.$$ 

Therefore we obtain the following:
Proposition 2.45. If $\sigma \notin \mathcal{O}_K^*/\mathcal{O}_K^{*2}$, then $2\text{-rk } \ker(\chi) \geq 2\text{-rk } \text{coker}(\chi)$, and

$$2\text{-rk } C(F) = \#\mathcal{R}(F/K) - 1 - [2\text{-rk } \ker(\chi) - 2\text{-rk } \text{coker}(\chi)].$$

If $\sigma \in \mathcal{O}_K^*/\mathcal{O}_K^{*2}$, then $2\text{-rk } \ker(\chi) \geq 1 + 2\text{-rk } \text{coker}(\chi)$ and

$$2\text{-rk } C(F) = \#\mathcal{R}(F/K) - [2\text{-rk } \ker(\chi) - 2\text{-rk } \text{coker}(\chi)].$$

2.3 Construction of $F/K$ with $h(F)$ Odd

Let $K$ be a totally real algebraic number field with absolute degree $[K : \mathbb{Q}] = n$ and $h^{+}(K) \equiv 1( \mod 2)$. We also assume that $K$ has exactly one dyadic prime ideal $D \subset \mathcal{O}_K$.

Let $K_D$ be the localization of $K$ at $D$. Then $\mathcal{O}_D$ is the ring of local integers. We are concerned with the local units $\mathcal{O}_D^*$ and their square classes $\mathcal{O}_D^{*2}/\mathcal{O}_D^{*2}$. There is a unique local square class $\epsilon_D \neq 1 \in \mathcal{O}_D^{*}/\mathcal{O}_D^{*2}$ for which $K_D(\sqrt{\epsilon_D})/K_D$ is an unramified quadratic extension. Then $\epsilon_D$ generates a subgroup of order 2 in $\mathcal{O}_D^{*}/\mathcal{O}_D^{*2}$ and the quotient of $\mathcal{O}_D^{*2}/\mathcal{O}_D^{*2}$ by this subgroup is denoted by $\Gamma$. There is also a localization homomorphism:

$$\nu_D : \mathcal{O}_K^{*}/\mathcal{O}_K^{*2} \to \Gamma.$$

Now, $2\text{-rk } \mathcal{O}_K^{*}/\mathcal{O}_K^{*2} = n = 2\text{-rk } \Gamma$. Thus

$$\mathcal{O}_K^{*}/\mathcal{O}_K^{*2} \cong \Gamma,$$

since every quadratic extension of $K$ has at least one ramified finite prime ideal. Hence for $1 \neq u \in \mathcal{O}_K^{*2}/\mathcal{O}_K^{*2}$ the single dyadic prime must ramify in $K(\sqrt{u})/K$.

Since $h^{+}(K) \equiv 1( \mod 2)$, there is for every prime ideal $P \subset \mathcal{O}_K$ a totally positive square $\pi_P \in K^*/K^{*2}$ for which $\text{ord}_P \pi_P \equiv 1( \mod 2)$ and $\text{ord}_{P'} \pi_P \equiv 0( \mod 2)$ if $P' \neq P$. Note that $\pi_P$ is a unique square class.
For $1 \neq \sigma \in K^*/K^{*2}$ we showed for the resulting quadratic extension $F/K = K(\sqrt{\sigma})/K$ that if $\sigma \notin \mathcal{O}_K^*/\mathcal{O}_K^{*2}$, then (see 2.45)

$$2\text{-rk } C(F) + 2\text{-rk ker}(\chi) - 2\text{-rk coker}(\chi) = \# \mathcal{R}(F/K) - 1.$$ 

Now this shows that $2\text{-rk ker}(\chi) - 2\text{-rk coker}(\chi)$ has a maximum value when $h(F) \equiv 1 \pmod{2}$.

We begin with the simplest case, $\# \mathcal{R}(F/K) = 1$. First, with $0 \leq k \leq n$, choose $k$ orderings of $K$. Then there is a unique square class $v \in \mathcal{O}_K^*/\mathcal{O}_K^{*2}$ which is positive in each of the chosen $k$ orderings and negative in the remaining $n - k$. Note that $v = 1 \in \mathcal{O}_K^*/\mathcal{O}_K^{*2}$ if and only if $k = n$.

For the unique dyadic prime ideal there is the square class generator $\epsilon_D \in K^*/K^{*2}$. We see that $D \subset \mathcal{O}_K$ is the only finite prime ramified in $F/K = K(\sqrt{\epsilon_D})/K$. Of course $n - k$ infinite primes also ramify. Thus $\# \mathcal{R}(F/K) = 1$, while $2\text{-rk } R^0(F/K) = n - k$ by [4] 4.2. Now we have the following

**Proposition 2.46.** The homomorphism $i_0 : H^0(C_2; \mathcal{O}_F^*) \to R^0(F/K)$ is an epimorphism.

**Proof.** Recall that $2\text{-rk } \text{im}(i_0) \geq n - k$. Thus, since $\text{im}(i_0) \subset R^0(F/K)$ we have:

$$n - k \leq 2\text{-rk } \text{im}(i_0) \leq 2\text{-rk } R^0(F/K) = n - k.$$ 

Hence $\text{im}(i_0) = R^0(F/K)$, and we are done. \[\square\]

Now, by [4] 9.1, it follows that $h(F) \equiv 1 \pmod{2}$. Also we obtain that

$$2\text{-rk } H^0(C_2; \mathcal{O}_F^*) = n - k.$$ 

The maximum value of $2\text{-rk ker}(\chi) - 2\text{-rk coker}(\chi)$ is 0 in this example. Actually $i_0$ is an isomorphism, hence $\chi$ is an epimorphism.
Let us now generalize the previous construction. Again with $0 \leq k \leq n$ choose $k$ orderings of $K$. Then choose an integer $s$, $0 < s \leq k$. Next choose $s$ non-negative integers $m_1, m_2, \ldots, m_s$ so that $m_1 + m_2 + \cdots + m_s = k$. Now partition the chosen $k$ orderings into pairwise disjoint subsets $M_1, M_2, \ldots, M_s$ with $\#M_i = m_i > 0$, $1 \leq i \leq s$.

Now we need some units $u_1, u_2, \ldots, u_s \in \mathcal{O}_K^*/(\mathcal{O}_K^*)^2$ such that each $u_i$ is negative with respect to all orderings in $M_i$ and positive at all other orderings of $K$ (we can do this since $K$ has units with independent signs). Then there is a $v \in \mathcal{O}_K^*/(\mathcal{O}_K^*)^2$ which is negative at all the remaining $n - k$ orderings of $K$ and positive for the first $K$ orderings already chosen. For each $u_i \in \mathcal{O}_K^*/(\mathcal{O}_K^*)^2$ we note $u_i$ cannot be trivial since $M_i \neq \emptyset$. For each $i$, $1 \leq i \leq s$, choose a non-dyadic prime ideal $P_i \subset \mathcal{O}_K$ such that $u_i$ is not a local square at $P_i$, but for $j \neq i$, $u_j$ is a local square at $P_i$. To see that this is possible, consider the extension

$$K(\sqrt{u_1}, \sqrt{u_2}, \ldots, \sqrt{u_s})/K$$

with Galois group elementary abelian of 2-rank $s$. Now for $1 \leq i \leq s$, there is a $\gamma_i \in \text{Gal}(K(\sqrt{u_1}, \sqrt{u_2}, \ldots, \sqrt{u_s})/K)$ such that if $j \neq i$, then $\gamma_i$ lies in the kernel of the epimorphism

$$\text{Gal}(K(\sqrt{u_1}, \sqrt{u_2}, \ldots, \sqrt{u_s})/K) \rightarrow \text{Gal}(K(\sqrt{u_j})/K) \rightarrow 1,$$

but for $j = i$, $\gamma_i \mapsto$ generator of $\text{Gal}(K(\sqrt{u_i})/K)$.

**Proposition 2.47.** The set of primes $P \subset \mathcal{O}_K$ with $\omega(P) = \gamma_i$ have positive density.

If $P$ is a prime $\mathcal{O}_K$-ideal as in Proposition 2.47, then $P$ is inert in $K(\sqrt{u_i})/K$, but $P$ splits in $K(\sqrt{u_j})/K$ if $j \neq i$. Then having selected our primes $P_1, P_2, \ldots, P_s$ (non-dyadic) we have the totally positive square class generators $\pi_1, \pi_2, \ldots, \pi_s$. 37
Now set

$$\sigma = v\pi_1\pi_2\cdots\pi_s \in K^*/K^{*2}.$$  

This $\sigma$ is positive in the originally chosen $k$ orderings, but negative in the remaining $n-k$. Note,

$$\text{ord}_{P_i}\sigma \equiv 1 \pmod{2}, \quad 1 \leq i \leq s.$$  

but

$$\text{ord}_{P}\sigma \equiv 0 \pmod{2}, \text{ if } P \neq P_1, P_2, \ldots, P_s.$$  

Hence $P_1, P_2, \ldots, P_s$ are the only non-dyadic primes ramified in $F/K = K(\sqrt{\sigma})/K$, $\sigma = v\pi_1\pi_2\cdots\pi_s$.

### 2.4 The Hilbert Symbol

We need Hilbert symbol computations. Let $L$ be a number field and let $L_p$ be the completion of $L$ at $p$ ($p$ prime of $L$ finite or infinite). For $a, b \in L_p^*$, the Hilbert symbol

$$(a, b)_p \in \{\pm 1\} = \mathbb{Z}^*$$

is defined as:

$$\begin{cases} 
+1 & \text{iff } a\alpha^2 + b\beta^2 = 1 \text{ has a solution } \alpha, \beta \in L_p \\
-1 & \text{otherwise} 
\end{cases}$$

In other words, $(a, b)_p = 1$ if and only if $a \in L_p^*$ is a norm from $L_p(\sqrt{b})$, if and only if $b \in L_p^*$ is a norm from $L_p(\sqrt{a})$.

At a complex infinite prime $p$ of $L$, we have $L_p \cong \mathbb{C}$, so the Hilbert symbol is trivial. At a real infinite prime $p$ of $L$ we have $L_p \cong \mathbb{R}$, the isomorphism corresponding to an embedding $\nu : L \to \mathbb{R}$. Then $(a, b)_p = -1$ if and only if $\nu(a), \nu(b) < 0$. Let us list the properties of Hilbert symbol:
1. \((x, y)_p = (y, x)_p\)

2. \((x, y)_p = 1\) if either \(x\) or \(y\) is a square in \(L^*_p\)

3. \((a, x)_p (b, x)_p = (ab, x)_p\) and \((x, u)_p (x, v)_p = (x, uv)_p\)

4. \((x, -x)_p = 1\)

5. \((x, x)_p = (x, -1)_p\)

6. \((x, 1 - x)_p = 1, x \neq 0, 1\)

Now, going back to our situation, there is no ordering of \(K\) at which \(u_i\) and \(\sigma\) are both negative, hence \((u_i, \sigma)_P = 1\), at every real infinite prime \(P\) of \(K\). Now if \(P \subset \mathcal{O}_K\) is a non-dyadic prime ideal \(P \notin \{P_1, P_2, \ldots, P_s\}\), then \(\text{ord}_P u_i \equiv \text{ord}_P \sigma \equiv 0\) (mod 2) so \((u_i, \sigma)_P = 1\). However, \((u_i, \sigma)_P = (u_i, \pi_i)_P = -1\) and \((u_i, \sigma)_P = 1\), for \(j \neq i\). To satisfy reciprocity we must have \((u_i, \sigma)_D = -1\) for the dyadic prime \(D\). Hence \(D\) also ramifies in \(F/K = K(\sqrt{\sigma})/K\). Thus \(\#\mathcal{R}(F/K) = s + 1\).

In \(\mathcal{O}_K^*/\mathcal{O}_K^{*2}\) the units \(u_1, u_2, \ldots, u_s\) generate a subgroup of 2-rank \(s\). Now, no non-trivial element of this subgroup can be a norm from \(F/K\), since \((u_i, \pi_j)_P = -1\) if and only \(i = j = k\). Hence, \(i_0 : H^0(C_2; \mathcal{O}_F^*) \to R^0(F/K)\) is an epimorphism. Thus

\[
h(F) \equiv h(K) \equiv 1 \pmod{2}
\]

and

\[
2\text{-rk } H^0(C_2; \mathcal{O}_F^*) = n - k + s.
\]

That is \(\ker(\chi) = \Pi\), while \(\text{coker}(\chi)\) is trivial.

We want to define a homomorphism

\[
l : H^0(C_2; C(F)_2) \to H^0(C_2; \mathcal{O}_F^*).\]
If \( a \in C(F)_2 \) and \( \bar{a} = a \), then represent \( a \) by an fractional \( \mathcal{O}_F \)-ideal \( A \subset F \). Since \( \bar{a} = a \), we may write \( \bar{A} = xA \), for some \( x \in F^* \). Then \( A = \bar{xA} = x\bar{x}A \), hence \( x\bar{x} \in \mathcal{O}_K^* \). We then set

\[
l(\text{cl}(a)) = \text{cl}(x\bar{x}) \in H^0(C_2; \mathcal{O}_F^*).
\]

Let us prove the following

**Lemma 2.48.** If \( a = \bar{a} \) in \( C(F)_2 \), then \( a \) can be represented by a fractional \( \mathcal{O}_F \)-ideal \( A \) for which \( \bar{A} = A \) if and only if \( l(\text{cl}(a)) = 1 \in H^0(C_2; \mathcal{O}_F^*) \).

**Proof.** Necessity: If \( \bar{A} = A \), then \( xA = A \), so \( x \in \mathcal{O}_F^* \). Then \( x\bar{x} = N_{F/K}(x) \in \mathcal{O}_K^* \) and also \( x\bar{x} \in N(\mathcal{O}_F^*) \), hence \( \text{cl}(x\bar{x}) = 1 \in H^0(C_2; \mathcal{O}_F^*) = \mathcal{O}_K^*/N(\mathcal{O}_F^*) \).

Sufficiency: Assume \( \bar{A} = xA \) and for some \( w \in \mathcal{O}_F^* \), \( w\bar{w} = x\bar{x} \), i.e. \( \text{cl}(x\bar{x}) = 1 \in H^0(C_2; \mathcal{O}_F^*) \). We can then write \( \bar{A} = xw^{-1}A \). But

\[
xw^{-1}(xw^{-1}) = xw^{-1}\bar{xw^{-1}} = \frac{x\bar{x}}{w\bar{w}} = 1,
\]

hence, by Hilbert 90, we may write

\[
z\bar{z}^{-1} = xw^{-1}, \quad \text{for some} \quad z \in F^*.
\]

Therefore \( \bar{A} = z\bar{z}^{-1}A \) or \( \bar{z}\bar{A} = zA \). Hence \( z\bar{A} = zA \). Thus, \( zA \) represents \( a \in C(F)_2 \) and \( \bar{zA} = zA \).

The ideal norm induces a homomorphism

\[
\mathcal{N} : C(F)_2 \rightarrow C(K)_2.
\]

For \( b \in C(F)_2 \), \( \mathcal{N}(b) = (\bar{b}) \), thus \( \mathcal{N}(b\bar{b}) = \mathcal{N}(b^2) = 1 \). As a consequence we regard \( \mathcal{N} \) as a homomorphism

\[
\mathcal{N} : H^0(C_2; C(F)_2) \rightarrow C(K)_2.
\]
Let us introduce
\[ \Gamma : H^0(C_2; C(F)_2) \to H^0(C_2; \mathcal{O}_F^*) \oplus C(K)_2, \]
by
\[ \Gamma(\text{cl}(a)) = (l(a), (a)) = (l(\text{cl}(a)), N(\text{cl}(a))). \]

We then have

**Theorem 2.49.** An ideal class \( a \in C(F)_2 \) lies in the image of \( \chi : \Pi \to C(F)_2 \) if and only if

(i) \( a = \bar{a} \) and

(ii) \( \Gamma(\text{cl}(a)) = (1, 1) \) in \( H^0(C_2; \mathcal{O}_F^*) \oplus C(K)_2. \)

**Proof.** “\( \Leftarrow \)” If \( a = \bar{a} \) and \( l(\text{cl}(a)) = 1 \in H^0(C_2; \mathcal{O}_F^*) \) we can choose a representative \( \mathcal{O}_F \)-ideal \( A \) with \( A = \bar{A} \) by Lemma 2.48. Since \( N(\text{cl}(a)) = 1 \in C(K)_2 \), we can write \( N(A) = y\mathcal{O}_K \) for some \( y \in K^* \). Without loss of generality we can take \( y \) to be totally positive since \( K \) contains units with independent signs. But now \( y\mathcal{O}_F = \mathcal{A}\mathcal{O}_F = A\bar{A} = A^2 \), which means that for \( y \in \Pi \) we have \( \chi(y) = a \in C(F)_2 \).

“\( \Rightarrow \)” We already have showed that \( \text{im}(\chi) \subset \ker(N) \) in Proposition 2.38. By the construction of \( \chi \) we can see that \( \chi(y) \) is always represented by an \( \mathcal{O}_F \)-ideal \( A \) with \( A = \bar{A} \). \( \square \)

**Corollary 2.50.** For every \( b \in C(F)_2 \) the product \( b\bar{b} \) lies in the image of \( \chi \).

In fact the homomorphism \( l \) introduced earlier is a composition
\[ H^0(C_2; C(F)_2) \to H^0(C_2; C(F)) \xrightarrow{d_0} H^0(C_2; \mathcal{O}_F^*). \]

We want to see what happens if we assume that the 2-primary subgroup of \( C(K) \) is an elementary abelian 2-group. Actually to make the discussion simpler
we assume

\[ C(K) = C(K)^2 \]

and later we point how to generalize. First an elementary

**Proposition 2.51.** If \( a = \bar{a} \in C(F)^2 \) is an element for which \( \text{cl}(a) \in H^0(C_2; C(F)) \) lies in the kernel of the natural homomorphism \( H^0(C_2; C(F)^2) \to H^0(C_2; C(F)) \), then \( a \in \text{im}(\chi) \).

*Proof.* We immediately see that \( l(\text{cl}(a)) = 1 \in H^0(C_2; \mathcal{O}_F^*) \) by regarding \( l \) as the composition

\[ H^0(C_2; C(F)^2) \to H^0(C_2; C(F)) \xrightarrow{d_0} H^0(C_2; \mathcal{O}_F^*). \]

Then we know that \( a = b\bar{b} \) for some \( b \in C(F) \). Thus

\[ \mathcal{N}(a) = \mathcal{N}(b\bar{b}) = \mathcal{N}(b)^2 \in C(K). \]

But \( C(K) = C(K)^2 \) and so \( \mathcal{N}(\text{cl}(a)) = 1 \in C(K)^2 = C(K) \). Hence, by Theorem 2.49, \( a \in \text{im}(\chi) \).

Associated to \( F/K = K(\sqrt{\sigma})/K \) there is a specific target subgroup \( T \subset C(K)^2 = C(K) \). This is the subgroup generated by the ideal classes of all finite prime ideals \( P \subset \mathcal{O}_K \) that ramify in \( F/K \).

**Lemma 2.52.** If \( a = \bar{a} \in C(F)^2 \) is represented by a fractional \( \mathcal{O}_F \)-ideal \( A \subset F \) with \( A = \bar{A} \), then \( \mathcal{N}(\text{cl}(a)) \in T \).

*Proof.* If \( P \subset \mathcal{O}_K \) is unramified, then either \( P\mathcal{O}_F = \mathcal{P} \) a prime ideal in \( \mathcal{O}_F \), or \( P\mathcal{O}_F = \mathcal{P}\bar{\mathcal{P}} \), a conjugate pair of prime ideals in \( \mathcal{O}_F \).

If \( P\mathcal{O}_F = \mathcal{P} \), then \( \text{ord}_P \mathcal{N}(A) = \text{ord}_P A\bar{A} = \text{ord}_P A^2 = 2\text{ord}_P A \).
If $PO_F = P\bar{P}$, then $\text{ord}_P N(A) = \text{ord}_P A + \text{ord}_P A = 2\text{ord}_P A$. Hence for all unramified finite prime ideals $P \subset \mathcal{O}_K$,

\[ \text{ord}_P N(A) \equiv 0 \pmod{2}. \]

Since $C(K)_2 = C(K)$, there is an $x \in K$ with

\[ \text{ord}_P x = \text{ord}_P N(A) \] at all unramified $P \subset \mathcal{O}_K$.

Thus, $x^{-1}N(A)$ is a fractional $\mathcal{O}_K$-ideal representing $N(\text{cl}(A)) = N(\text{cl}(a)) \in T$. 

\[ \square \]

Next suppose $B$ is a fractional ideal for which $\text{ord}_P B = 0$, for all unramified ideals $P \subset \mathcal{O}_K$. Then $B\mathcal{O}_F = A^2$, for a unique fractional $\mathcal{O}_F$-ideal $A$. Surely $\bar{A} = A$, but is $\text{cl}(A) = a$ actually in the subgroup $C(F)_2$? It is if and only if $B\mathcal{O}_F$ is a principal ideal. That is, if $b \in T \subset C(K)_2 = C(K)$, then $b$ lies in the image of $N : \ker(l) \to T$ if and only if $i_*(b) = 1 \in C(F)_2 \subset C(F)$, where $i_*$ is the natural homomorphism $C(K) = C(K)_2 \to C(F)_2 \subset C(F)$. Thus we let $\ker(l) \subset C(F)_2$ be all $a = \bar{a} \in C(F)_2$ for which $l(\text{cl}(a)) = 1 \in H^0(C_2; \mathcal{O}_F^\times)$. Let us summarize:

**Proposition 2.53.** If the 2-primary subgroup of $C(K)$ is elementary abelian, then the sequence

\[ 1 \to \ker(\chi) \to \Pi \xrightarrow{\chi} \ker(l) \xrightarrow{N} T \xrightarrow{i_*} C(F)_2 \]

is exact.

Let us add that the target group $T$ is trivial if the ideal class of every ramified prime ideal has odd order in $C(K)$. In particular, if $F/K$ is unramified, then $T$ is trivial. If we assume $H^0(C_2; \mathcal{O}_F^\times) \to R^0(F/K)$ is a monomorphism it will follow that $l$ is trivial, so $\ker(l) = \{a \mid a = \bar{a} \in C(F)_2\}$. 

43
2.5 Elementary Abelian 2-groups

Let $G$ denote an elementary abelian 2-group which will be multiplicatively written. The important point is that for every $g \in G$, we have $g^{-1} = g$. Next we assume that the cyclic group of order 2, $C_2$, acts as a group of automorphisms on $G$. We denote this by $g \rightarrow \bar{g}$, for $g \in G$. Thus are defined the cohomology groups $H^0(C_2; G)$ and $H^1(C_2; G)$. Let us prove

**Lemma 2.54.** For $G$ an elementary abelian 2-group acted on only by $C_2$ we have $H^0(C_2; G) = H^1(C_2; G)$.

**Proof.** We first observe for $g \in G$ that $\bar{g} = g$ if and only if $\bar{g} = g^{-1}$. Furthermore, for $h \in G$, $h\bar{h} = h\bar{h}^{-1}$. □

In our situation $C(F)_2$ is a finite elementary abelian 2-group acted on by the Galois group of the quadratic extension. Thus, by Lemma 2.54, $H^1(C_2; C(F)_2) = H^0(C_2; C(F)_2) = H^0(C_2; C(F))$. Referring to the exact hexagon 1.18, the natural homomorphism $H^1(C_2; C(F)_2) \rightarrow H^1(C_2; C(F))$ is composed with

$$d_1 : H^1(C_2; C(F)) \rightarrow H^1(C_2; \mathcal{O}_F^*)$$

to produce the homomorphism

$$\eta : H^1(C_2; C(F)_2) \rightarrow H^1(C_2; \mathcal{O}_F^*).$$

Recall also the homomorphism $l$ on page 39. Thus we get the following diagram:
These two homomorphisms \( l \) and \( \eta \) may be directly described.

If \( a \in C(F)_2 \) and \( \bar{a} = a \) then represent \( a \) by a fractional \( \mathcal{O}_F \)-ideal \( A \). First we write \( \bar{A} = xA \) for some \( x \in F^* \). Then \( A = \bar{A} = \bar{x}A = x\bar{x}A \), hence \( x\bar{x} \) is a unit in \( \mathcal{O}_F^* \). Thus \( l(a) \) is the cohomology class of \( x\bar{x} \) in \( H^0(C_2; \mathcal{O}_F^*) \). However, \( A^{-1} \sim A \), \( \bar{A}^{-1} \sim \bar{A} \). Thus, for \( a = \bar{a} \) we also know that \( A\bar{A} \) is a principal ideal. That is

\[
A\bar{A} = z\mathcal{O}_F, \text{ for some } z \in F^*.
\]

Thus \( z\mathcal{O}_F = \bar{A}A = A\bar{A} = z\mathcal{O}_F \). Hence \( z\bar{z}^{-1} \in \mathcal{O}_F^* \) and this defines a class in \( H^1(C_2; \mathcal{O}_F^*) \). So \( \eta : H^0(C_2; C(F)_2) \to H^1(C_2; \mathcal{O}_F^*) \) is also described.

What does this mean? If \( a = \bar{a} \) we have \( \text{cl}(a) \in H^0(C_2; C(F)_2) = H^1(C_2; C(F)_2) \).

There is a fractional \( \mathcal{O}_F \)-ideal \( A \) representing \( a \in C(F)_2 \) and for which \( \bar{A} = A \) if and only if

\[
l(\text{cl}(a)) = 1 \in H^0(C_2; \mathcal{O}_F^*).
\]

Assume then \( A = \bar{A} \). We have \( A\bar{A} = A^2 = z\mathcal{O}_F \) and \( \bar{A}^2 = A^2 = z\mathcal{O}_F \). If \( z\bar{z}^{-1} = 1 \in H^1(C_2; \mathcal{O}_F^*) \), then \( v\bar{v}^{-1} = z\bar{z}^{-1} \) for some \( v \in \mathcal{O}_F^* \). Hence \( \bar{z}v = z\bar{v} \), that is \( (\bar{z}v) = z\bar{v} = \bar{z}v \). Therefore \( A^2 = y\mathcal{O}_F \) for some \( y \in K^* \). We see that \( \mathcal{N}(A) \) is principal in \( K \) with generator \( y \). Thus we have

**Proposition 2.55.** If \( \bar{a} = a \in C(F)_2 \), then \( a \) lies in the image of \( \chi : \Pi \to C(F)_2 \) (i.e. \( \chi(y) = a \)) if and only if \( \text{cl}(a) \in H^0(C_2; C(F)_2) \) lies in the kernel of both \( l \) and \( \eta \).

Let us make some comments. If \( F/K \) is ramified, then for \( i_* : C(K) \to C(F) \), \( \ker(i_*) \) embeds in \( H^1(C_2; \mathcal{O}_F^*) \). Furthermore \( \ker(\eta) \subset \ker(i_*) \subset H^1(C_2; \mathcal{O}_F^*) \). As long as \( F/K \) is ramified we can also embed \( C(K)_2 \) into \( \Pi \). That is we also have \( \ker(i_*) \subset \ker(\chi) \), so

\[
2 \text{-rk } \ker(\eta) \leq 2 \text{-rk } \ker(i_*) \leq 2 \text{-rk } \ker(\chi) \leq k.
\]
If $\ker(\chi)$ is trivial, then also $\ker(i_*)$ and $\im(\eta)$ are trivial, and hence all $a = \bar{a} \in C(F)_2$ lie in the image of $\chi$.

### 2.6 Star Extensions

We have noted (see 2.1) that there is a natural isomorphism $C(K)_2 \cong E^+$. Now if $F/K = K(\sqrt{\sigma})/K$ is a quadratic extension of $K$, then $S \subseteq \Omega_K$ consists of all infinite primes in $K$ together with all finite primes in $K$ that ramify in $F/K$.

Recall (page 19) $E^+_S \subset K^*/K^{*2}$, the subgroup of all totally positive square classes $y \in K^*/K^{*2}$ with $\ord_P y \equiv 0 \pmod{2}$ at all $P \in \mathcal{O}_K, P \notin S$. Clearly $E^+ \subset E^+_S$.

The subgroup $\Pi$ can be regarded as a quotient group of $E^+_S$.

If $F/K$ is ramified then $C(K)_2$ embeds into $\Pi$, see 2.3, thus

$$C(K)_2 \subset \Pi.$$ 

Then, the restriction of $\chi : \Pi \to C(F)_2$ agrees with the restriction of the natural homomorphism $i_* : C(K) \to C(F)$ to the subgroup $C(K)_2$. We must note that $\ker(i_*)$ is entirely contained in $C(K)_2$. Hence we can say

$$\ker(i_*) \subset \ker(\chi)$$

if $F/K$ is ramified.

Our only concern is when $2\text{-rk } C(K)_2 > 0$.

**Definition 2.56.** A quadratic extension $F/K = K(\sqrt{\sigma})/K$ is a star extension (in short $\ast$-ext.) if and only if

1. $\sigma$ is totally positive;

2. no finite dyadic prime in $\Omega_K$ ramifies in $F/K$;

3. at least one finite non-dyadic prime in $\Omega_K$ does ramify;
4. \(2\text{-rk} C_S(K) < 2\text{-rk} C(K)\);

5. \(#\mathcal{R}(F/K) + 2\text{-rk} C_S(K) = 1 + 2\text{-rk} C(K)\).

Remember that \(#\mathcal{R}(F/K)>0\). Thus a \(*\text{-ext.} F/K\) is a ramified totally real quadratic extension of \(K\). Furthermore, \(\sigma \notin \mathcal{O}_K^*/\mathcal{O}_K^{*2}\) and \(\sigma \notin E^+\) (see 2.35 on page 26). Hence \(C(K)_2 \subset \Pi\). But now remember (see Lemma 2.26) that

\[
2\text{-rk} \Pi = #\mathcal{R}(F/K) + 2\text{-rk} C_S(K) - 1,
\]

which together with our assumption

\[
#\mathcal{R}(F/K) + 2\text{-rk} C_S(K) = 1 + 2\text{-rk} C(K)
\]
yields:

\[
2\text{-rk} \Pi = 2\text{-rk} C(K).
\]

As a result, for \(*\text{-ext.}\) we have

\[
\Pi = C(K)_2.
\]

Immediately we see

**Proposition 2.57.** If \(F/K\) is a quadratic \(*\text{-ext.}\) then

(i) \(\ker(i_*) = \ker(\chi)\)

(ii) \(2\text{-rk} \ker(i_*) = 2\text{-rk} H^0(C_2; \mathcal{O}_F^*)\)

(iii) \(1 + 2\text{-rk} \ker(i_*) = 2\text{-rk} H^1(C_2; \mathcal{O}_F^*)\)

**Proof.** Since \(\sigma\) is totally positive we have \(n = k\). Using Theorem 2.32 and Corollary 2.33(i) the assertions follow. \(\blacksquare\)
Since we are only concerned with the case $2\text{-}\text{rk } C(K) > 0$ and $\#\mathcal{R}(F/K) \geq 1$, we see that $\#\mathcal{R}(F/K) \geq 2$ for a $\ast$-ext. We shall refer to the exact hexagon 1.18 to regard $\ker(i_\ast) \subset H^1(C_2; \mathcal{O}_F^\ast)$ as the image of the homomorphism

$$d_1 : H^1(C_2; C(F)) \rightarrow H^1(C_2; \mathcal{O}_F^\ast),$$

thus $\text{im}(d_1) \subset H^1(C_2; \mathcal{O}_F^\ast)$ has index 2. Let us show

**Proposition 2.58.** If $F/K$ is a $\ast$-ext. for which every unit in $\mathcal{O}_K^\ast$ is a field norm from $F/K$, then

$$2\text{-}\text{rk } H^1(C_2; \mathcal{O}_F^\ast) = \#\mathcal{R}(F/K) - 1 + 2\text{-}\text{rk } H^0(C_2; \mathcal{O}_F^\ast).$$

*Proof.* We refer to the exact hexagon 1.18. The homomorphism $i_0 : H^0(C_2; \mathcal{O}_F^\ast) \rightarrow R^0(F/K)$ is trivial since every unit in $\mathcal{O}_K^\ast$ is a norm from $F/K$. Hence

$$j_1 : R^0(F/K) \rightarrow H^1(C_2; C(F))$$

is a monomorphism. Since

$$2\text{-}\text{rk } R^0(F/K) = \#\mathcal{R}(F/K) - 1$$

and

$$2\text{-}\text{rk } \text{im}(d_1) = 2\text{-}\text{rk } H^0(C_2; \mathcal{O}_F^\ast)$$

the proposition follows. \qed

Note that the assumption that units in $\mathcal{O}_K^\ast$ are all norms from $F/K$ does not imply that $H^0(C_2; \mathcal{O}_F^\ast)$ is trivial. Let us now turn to another extreme:

**Proposition 2.59.** If $F/K$ is $\ast$-ext. for which

$$i_0 : H^0(C_2; \mathcal{O}_F^\ast) \rightarrow R^0(F/K)$$

is an epimorphism, then

$$2\text{-}\text{rk } H^1(C_2; C(F)) = 2\text{-}\text{rk } \ker(i_\ast) = 2\text{-}\text{rk } H^0(C_2; C(F)) \geq \#\mathcal{R}(F/K) - 1.$$
Proposition 2.60. Let $F/K$ be a $\ast$-ext. for which $2\text{-rk } C(K) \leq n$. If $\#\mathcal{R}(F/K) = 1 + 2\text{-rk } C(K)$ and if $i_0$ is an epimorphism then

$$2\text{-rk } H^1(C_2; C(F)) = 2\text{-rk } C(K) = 2\text{-rk } H^0(C_2; \mathcal{O}_F^*) = 2\text{-rk } \ker(i_\ast).$$

Proof. This follows from the previous proposition by noting that $2\text{-rk } \ker(i_\ast) \leq 2\text{-rk } C(K) = \#\mathcal{R}(F/K) - 1$. \hfill $\square$

We must turn to the question of existence of $\ast$-ext. All infinite primes of $K$ are real. The number of finite dyadic primes of $K$ is denoted by $g_2(K)$, $1 \leq g_2(K) \leq n = [K : \mathbb{Q}]$. The cycle $c_D$ on $K$ will consist of all real infinite primes of $K$, each, as usual, with multiplicity one. Each finite dyadic prime $D \subset \mathcal{O}_K$ will appear in $c_D$. If $e_D$ is the ramification index of the dyadic prime, then the ramification index of the dyadic prime in $c_D$ is $2e_D$.

Now, if $\sigma \in K^\ast$, and $\sigma \equiv 1 \pmod {\ast c_D}$ then $\sigma$ is totally positive and at each dyadic ideal $D \subset \mathcal{O}_K$ this $\sigma$ is a local unit modulo $\mathcal{P}_D^{2e_D}$ where $\mathcal{P} \subset \mathcal{O}_D$ is the maximal ideal in the local ring of integers at $D$.

Thus, if $\sigma \equiv 1 \pmod {\ast c_D}$, then $F = K(\sqrt{\sigma})/K$ is a totally real quadratic extension of $K$ in which no dyadic prime of $K$ ramifies. A finite non-dyadic prime ideal $P \subset \mathcal{O}_K$ ramifies if and only if $\text{ord}_P \sigma \equiv 1 \pmod 2$. Let $C(K, c_D)$ be the generalized ideal class group associated to $c_D$. This is a finite abelian group with a natural epimorphism

$$C(K, c_D) \rightarrow C(K) \rightarrow 1.$$

Clearly, $F/K$ is a $\ast$-ext. if and only if $\sigma \equiv 1 \pmod {\ast c_D}$ and $\text{ord}_P \sigma \equiv 1 \pmod 2$ for at least one finite non-dyadic prime $P \subset \mathcal{O}_K$.

Let us choose a minimal generating set $u_1, u_2, \ldots, u_n$ for $\mathcal{O}_K^*/\mathcal{O}_K^{2\ast}$. Let us consider the extension field $L/K$ which is the compositum of the quadratic extensions

$$K(\sqrt{u_j})/K, \ 1 \leq j \leq n.$$
This extension contains the square root of every unit in $\mathcal{O}_K^*$. The Galois group $\text{Gal}(L/K)$ is an elementary abelian 2-group with $2\text{-rk } \text{Gal}(L/K) = n$. Then we can give a minimal generating set $b_1, b_2, \ldots, b_n$ as follows. For each $j$, $1 \leq j \leq n$, let $b_j \in \text{Gal}(L/K)$ be the unique element for which the image of $b_j$ under

$$\text{Gal}(L/K) \to \text{Gal}(K(\sqrt{u_j})/K) \to 1$$

is the generator of $\text{Gal}(K(\sqrt{u_j})/K)$, but for $i \neq j$, $1 \leq i \leq n$, the image of $b_i$ under

$$\text{Gal}(L/K) \to \text{Gal}(K(\sqrt{u_i})/K) \to 1$$

is trivial in $\text{Gal}(K(\sqrt{u_i})/K)$.

No finite non-dyadic prime ideal of $K$ ramifies. Thus, if $P \subset \mathcal{O}_K$ is a finite non-dyadic prime ideal of $K$ then it has an Artin symbol

$$A(P, L/K) \in \text{Gal}(L/K).$$

If the Artin symbol is trivial, then every unit in $\mathcal{O}_K^*/\mathcal{O}_K^{*2}$ is a local square at $P$, but if $A(P, L/K) = b_j$, then $u_j$ is not a local square at $P$, while for $i \neq j$, $u_i$ is a local square at $P$.

To simplify our treatment we assume $C(K)$ is a 2-group (not necessarily elementary abelian). Let $H/K$ be the Hilbert class field of $K$. No prime ideal of $K$ ramifies in $H/K$. The Artin symbol induces the isomorphism

$$A : C(K) \to \text{Gal}(H/K).$$

Now we can express the finite abelian 2-group as a direct product of cyclic factors. Then the number of such cyclic factors is $2\text{-rk } C(K) = r > 0$. For each of our chosen cyclic factors we pick a generator $\beta_1, \beta_2, \ldots, \beta_r \in C(K)$. Then

$$A(\beta_j, L/K) = b_j \in \text{Gal}(H/K)$$
will be generators of the corresponding cyclic factors in the associated direct product splitting of \( \text{Gal}(H/K) \). There is, of course, the extension field \( HL/K \). As \( H/K \) is unramified and every subfield of \( L/K \) is ramified, the composition \( HL/K \) has

\[
\text{Gal}(HL/K) \cong \text{Gal}(H/K) \times \text{Gal}(L/K).
\]

For each \( g \in \text{Gal}(HL/K) \) the density of the finite non-dyadic primes \( P \) with \( A(P, HL/K) = g \) is

\[
\frac{1}{[H : K] \cdot [L : K]} = \frac{1}{\#C(K) \cdot 2^n}.
\]

At this point let us construct \(*\)-ext. for which every unit in \( \mathcal{O}_K^* \) is a field norm from \( F/K \).

Choose \( l, 1 \leq l \leq r = 2 \cdot \text{rk} C(K) \). Now select finite non-dyadic prime ideals in \( \mathcal{O}_K, P_1, P_2, \ldots, P_l \) so that

\[
A(P_j, HL/K) = (\beta_j, \text{id}), \quad \text{for } 1 \leq j \leq l.
\]

Thus \( A(P_j, L/K) = \text{id} \in \text{Gal}(L/K) \) and hence every unit is a local square at each \( P_j \). Next we choose one more finite non-dyadic prime ideal \( Q \subset \mathcal{O}_K \) so that the product \( P_1 \cdot P_2 \cdots P_l \cdot Q \) has trivial generalized class in \( C(K, c_D) \). Thus there is a \( \sigma \in K^*, \sigma \equiv 1 \mod{c_D} \), generating the product \( P_1 \cdot P_2 \cdots P_l \cdot Q \).

If we form \( F/K = K(\sqrt{\sigma})/K \), then \( \#R(F/K) = l + 1 \), that is \( P_1, P_2, \ldots, P_l, Q \) ramify. Moreover \( l + 2 \cdot \text{rk} C_S(K) = 2 \cdot \text{rk} C(K) \) in this construction and hence we have a \(*\)-ext.. Every unit \( u \in \mathcal{O}_K^*/\mathcal{O}_K^{*2} \) is a norm from \( F/K \). First \( \sigma \) is totally positive. At each dyadic prime ideal \( D, \sigma \) is a local unit which is either a local square or the local unit for which \( K_D(\sqrt{\sigma})/K_D \) is the unit non-trivial local unramified extension.

For each \( P_j, 1 \leq j \leq l \), all units are local squares. Thus \( (u, \sigma)_P = 1 \) at every prime ideal of \( K \), except possibly for \( Q \), where \( u \in \mathcal{O}_K^* \). By Hilbert symbol reciprocity, \( (u, \sigma)_Q = 1 \) also. Hence, \( u \) is a field norm from \( F/K \) for every \( u \in \mathcal{O}_K^* \).
Next, let us assume $1 \leq l \leq \min(n; 2 \cdot \text{rk } C(K))$. We may consider the pairs $(B_j, b_j) \in \text{Gal}(HL/K)$, $1 \leq j \leq l$. So there are finite non-dyadic prime ideals $P_1, P_2, \ldots, P_l$ with

$$A(P_j, HL/K) = (B_j, b_j) \in \text{Gal}(HL/K).$$

Then $A(P_j, H/K) = B_j$ corresponding to a generator of a cyclic factor of $C(K)$, while $A(P_j, L/K) = b_j \in \text{Gal}(L/K)$ which means $u_j$ is not a local square at $P_j$, but is a local square at each $P_i$, $i \neq j$, $1 \leq i \leq l$.

Choose another non-dyadic prime ideal $Q$ with $P_1 \cdot P_2 \cdot \cdots \cdot P_l \cdot Q$ principal in $C(K, cD)$. Thus $\sigma$ generates this product with $\sigma \equiv 1 \pmod{cD}$.

Let us turn to $F/K = K(\sqrt{\sigma})/K$. This is a $*$-ext. Let us check Hilbert symbols. Take a unit $u_j \in O_K^*$. Then $\text{ord}_{P_j} \sigma \equiv 1 \pmod{2}$ and $u_j$ is not a local square at $P_j$. Thus

$$(u_j, \sigma)_{P_j} = -1.$$

However $u_j$ is a local square at $P_i$, $i \neq j$. Thus

$$(u_j, \sigma)_{P_i} = 1, \text{ for } i \neq j.$$

The only other prime ideal at which the Hilbert symbol of $u_j$ and $\sigma$ is $-1$ is

$$(u_j, \sigma)_{Q} = -1.$$

Thus $u_1, u_2, \ldots, u_l$ generate a subgroup of $O_K^*/O_K^{*2}$ with 2-rank equal to $l$. But no other element of this subgroup besides the identity can be a norm from $F/K$. Thus $O_K^*/O_K^{*2}$ contains a subgroup of rank $l$, generated by $u_1, u_2, \ldots, u_l$, which maps isomorphically into $R^0(F/K)$ by $i_0$. Hence, since $2 \cdot \text{rk } R^0(F/K) = l = \#R(F/K) - 1$ we see that $i_0 : H^0(C_2; O_F^*) \to R^0(F/K) \to 1$ is an epimorphism. Hence

$$2 \cdot \text{rk } H^1(C_2; C(F)) = 2 \cdot \text{rk } \ker(i_*) = 2 \cdot \text{rk } H^0(C_2; O_F^*) \geq l = \#R(F/K) - 1.$$
Now obviously

$$2 \text{-rk } H^0(C_2; \mathcal{O}_F^\times) = 2 \text{-rk } \ker(i_*) \leq n$$

while

$$2 \text{-rk } \ker(i_*) \leq 2 \text{-rk } C(K).$$

Thus, if $2 \text{-rk } C(K) \leq n$, we may take $l = 2 \text{-rk } C(K)$ in the preceding construction to produce a $*$-ext. $F/K$ with $2 \text{-rk } C(K) \leq 2 \text{-rk } \ker(i_*) \leq 2 \text{-rk } C(K)$. Thus

$$2 \text{-rk } \ker(i_*) = 2 \text{-rk } C(K) = 2 \text{-rk } H^0(C_2; \mathcal{O}_F^\times) = 2 \text{-rk } H^1(C_2; C(F)).$$

Finally, if $n \leq 2 \text{-rk } C(F)$ we can always use $l = n$. We then have

$$2 \text{-rk } \ker(i_*) = n = 2 \text{-rk } H^0(C_2; C(F)) = 2 \text{-rk } H^1(C_2; C(F)).$$

Let us make some comments. For $*$-ext. we can identify $C(K)_2$ with $\Pi$ and hence $\ker(\chi)$ with $\ker(i_*)$. Combining what we know of $\ker(\chi)$ with the small amount of information we had about $\ker(i_*) \subset H^1(C_2; \mathcal{O}_F^\times)$ as the image of $d_1$ we can use the exact hexagon to produce a great deal of information about $\ker(i_*)$ as well as $H^1(C_2; C(F))$. Thus, $*$-ext. seems to be very worthwhile commenting on.

### 2.7 Examples

Assume $K$ is totally real containing units with independent signs and $[K : \mathbb{Q}] = n \geq 2$. Since $K$ has units with independent signs, for every ordering of $K$ there will be a unit positive in only that ordering and negative in the remaining $n - 1$ orderings of $K$. Denote by $v \in \mathcal{O}_K^\times/\mathcal{O}_K^2$ the square class of such a unit. There is a natural one-to-one correspondence between these square classes and the orderings of $K$.

For a choice of $v \in \mathcal{O}_K^\times/\mathcal{O}_K^2$ form the quadratic extension

$$F/K = K(\sqrt{v})/K.$$
Then \( n - 1 \) infinite primes ramify in \( F/K \) and one ordering of \( K \) splits into a conjugate pair of orderings in \( F \). Thus \( r_1(F) = 2 \), and \( r_2(F) = n - 1 \).

Since \( C^+(K) \cong C(K) \) there must be at least one finite prime in \( \mathcal{O}_K \) that ramifies in \( F/K \). Since \( v \) is a unit, all finite ramified primes must be dyadic.

By Theorem 2.26 we have that

\[
2\text{-rk } \Pi = \# \mathcal{R}(F/K) + 2\text{-rk } C_S(K).
\]

Now Corollary 2.33 says

\[
1 + 2\text{-rk } H^0(C_2; \mathcal{O}_F^*) = n - 1 + 2\text{-rk } \ker(\chi),
\]

while Theorem 2.32 gives

\[
2\text{-rk } H^1(C_2; \mathcal{O}_F^*) = 2\text{-rk } \ker(\chi).
\]

Up to square classes, the only non-trivial element of \( \mathcal{O}_K^*/\mathcal{O}_K^{*2} \) that can be a field norm from \( F/K \) is \(-v\) which is the norm of the unit \( \sqrt{v} \in \mathcal{O}_F^* \). Thus

\[
2\text{-rk } H^0(C_2; \mathcal{O}_F^*) = n - 1,
\]

and so

\[
2\text{-rk } \ker(\chi) = 1 = 2\text{-rk } H^1(C_2; \mathcal{O}_F^*).
\]

Now Corollary 2.37 implies that \( \mathcal{O}_F^* \) has also units with independent signs.

If \( h(K) \) is odd, then Proposition 2.42 implies that \( \chi : \Pi \to C(F)_2 \) is onto, hence

\[
2\text{-rk } C(F) = \# \mathcal{R}(F/K) - 1,
\]

by Proposition 2.45.

On the other hand, if \( h(K) \) is even we see that \( 2\text{-rk } \ker(i_*) \leq 1 \) by Lemma 2.35.

Now we still have, by Theorem 4.2 [4], that

\[
2\text{-rk } R^0(F/K) = \# \mathcal{R}(F/K) + n - 2.
\]
Looking at the exact hexagon, we see that $i_0 : H^0(C_2; \mathcal{O}_F^*) \to R^0(F/K)$ is a monomorphism. Now Theorem 5.1 [4] says that

$$2 \text{-rk } R^1(F/K) = \# \mathcal{R}(F/K).$$

Thus,

$$j_0 : R^1(F/K) \to H^0(C_2; C(F))$$

is onto. Let us summarize:

**Theorem 2.61.** Let $K$ be a totally real number field having units with independent signs. Let $v \in \mathcal{O}_K^*$ be a unit which is positive with respect to exactly one ordering of $K$ and negative with respect to the remaining $n - 1$ orderings of $K$, where $n = [K : \mathbb{Q}] \geq 2$. Put $F = K(\sqrt{v})$.

If $\ker(i_*)$ is trivial, then

$$2 \text{-rk } H^0(C_2; C(F)) = \# \mathcal{R}(F/K) - 1.$$

If $\ker(i_*)$ is cyclic of order 2, then

$$2 \text{-rk } H^0(C_2; C(F)) = \# \mathcal{R}(F/K).$$

Let us be more specific. Let $N > 1$ be a square free rational integer so that $N \equiv 1 \pmod{8}$. Then $K = \mathbb{Q}(\sqrt{N})$ has a conjugate pair of dyadic primes $D, D^*$ in $\mathcal{O}_K$. Each completion, $K_D$ and $K_{D^*}$, can be identified with the 2-adic rationals $\mathbb{Q}_2$ as follows.

Since $N \equiv 1 \pmod{8}$, $N$ has two distinct square roots, $v$ and $-v$, in the units of the 2-adic integers $\mathbb{Z}_2^*$. Then, embed $K = \mathbb{Q}(\sqrt{N})$ into $\mathbb{Q}_2$ in two ways:

$$r + s\sqrt{N} \mapsto r + sv \in \mathbb{Q}_2,$$

$$r + s\sqrt{N} \mapsto r - sv \in \mathbb{Q}_2.$$
Thus, the localizations $K_D$ and $K_{D^*}$ are identified with $\mathbb{Q}_2$.

We now assume that the norm of the fundamental unit $\epsilon \in \mathcal{O}_K^*$ is $-1$. Then, let

$$F/K = K(\sqrt{\epsilon})/K.$$  

We can show:

**Proposition 2.62.** *Only one dyadic prime of $K$ ramifies in $F/K$.***

**Proof.** Note that $\epsilon \cdot \epsilon^* = -1$. That is, in $\mathbb{Z}_2^*$, $\epsilon$ and $\epsilon^*$ are a pair of units with $\epsilon \cdot \epsilon^* = -1$. Also note that

$$\mathbb{Z}_2/8\mathbb{Z}_2 \cong \mathbb{Z}/8\mathbb{Z}.$$ 

If $\alpha, \beta \in \mathbb{Z}/8\mathbb{Z}$ with $\alpha \cdot \beta = -1$, then $\alpha, \beta \in (\mathbb{Z}/8\mathbb{Z})^*$ and so $(\alpha, \beta)$ is one of $(1, 7); (7, 1); (3, 5); (5, 3)$. Observe that

$$\mathbb{Q}_2(\sqrt{7})/\mathbb{Q}_2, \text{ and } \mathbb{Q}_2(\sqrt{3})/\mathbb{Q}_2$$ 

are locally ramified. However, $\mathbb{Q}_2(\sqrt{5})/\mathbb{Q}_2$ is the unique unramified local quadratic extension, while $\mathbb{Q}_2(\sqrt{1})/\mathbb{Q}_2$ is trivial, and so unramified. Thus we can see that only one dyadic prime ideal of $K$ ramifies in $F/K$. 

\[\square\]
3. Density Results

Using Chebotarev’s Theorem we will prove that the four sets of primes:

\[ X_1 = \{ p \text{ prime} : p \equiv 1 \pmod{16}, p \in A^+(2) \} \]
\[ X_2 = \{ p \text{ prime} : p \equiv 1 \pmod{16}, p \in A^-(2) \} \]
\[ X_3 = \{ p \text{ prime} : p \equiv 9 \pmod{16}, p \in A^+(2) \} \]
\[ X_4 = \{ p \text{ prime} : p \equiv 9 \pmod{16}, p \in A^-(2) \} \]

have equal natural densities in the set of all primes.

3.1 Background

We will define the notions of Dirichlet Density, natural density and we will see how the Artin symbol is related to the splitting behavior of primes. Also we will state the Chebotarev’s Theorem which we will use in the next section.

Definition 3.63. A set \( \mathcal{P} \) of prime numbers has Dirichlet Density \( d(\mathcal{P}) \), if

\[ \lim_{s \to 1^+} \frac{\sum_{p \in \mathcal{P}} p^{-s}}{\sum_{p \text{ prime}} p^{-s}} \]

exists and equals \( d(\mathcal{P}) \).

Another notion of density, which we find it to be more natural is:

Definition 3.64. A set \( \mathcal{P} \) of prime numbers has natural density \( \Delta(\mathcal{P}) \) if

\[ \lim_{n \to \infty} \frac{|\{ p \leq n : p \in \mathcal{P} \}|}{|\{ p \leq n : p \text{ prime} \}|} \]

exists and equals \( \Delta(\mathcal{P}) \).

If a set of primes has natural density, then it has Dirichlet density and the two densities are equal, see [24], page 252.

In 1837, Dirichlet proved the famous theorem:
Theorem 3.65. Let $n$ be a positive integer. Then for each $a$ such that $(a, n) = 1$, the set of prime numbers $p$ such that $p \equiv a \pmod{n}$ has natural density $1/\phi(n)$.

Here, $\phi(n)$ denotes the Euler function, namely:

$$\phi(n) = |\{d : (d, n) = 1\}|$$

The most important consequence of this theorem is that in any arithmetic progression $a, a+n, a+2n, ...$ where $(a, n) = 1$, there are infinitely many prime numbers.

Now we will introduce the Artin symbol. First we have the following lemma:

Lemma 3.66. Let $K \subset L$ be a Galois extension, and let $p$ be a prime of $\mathcal{O}_K$ which is unramified in $L$. If $q$ is a prime of $\mathcal{O}_L$ containing $p$, then there is a unique element $\sigma \in \text{Gal}(L/K)$ such that

$$\sigma(\alpha) \equiv \alpha^{N(p)} \pmod{q}, \text{ for all } \alpha \in \mathcal{O}_L,$$

where $N(p) = |\mathcal{O}/p|$ is the norm of $p$.

The proof of this lemma can be found in [6], for example.

Definition 3.67. The unique element $\sigma$ in Lemma 3.66, is called the Artin Symbol. We will denote this symbol by $\left(\frac{L/K}{q}\right)$ as it depends on $K, L$ and $q$.

Now we list the properties of the Artin symbol which are going to be used in the next section.

Lemma 3.68. Let $K \subset L$ be a Galois extension, and let $p$ be a prime of $\mathcal{O}_K$ which is unramified in $\mathcal{O}_L$. Given $q$ a prime of $\mathcal{O}_L$ containing $p$, we have:

(i) $p$ splits completely in $\mathcal{O}_L$ if and only if $\left(\frac{L/K}{q}\right) = \text{id}$

(ii) If $K = \mathbb{Q}$, then $\left(\frac{L/K}{p}\right) = \{g\} \subset \text{Z}(\text{Gal}(L/\mathbb{Q}))$ if and only if $p$ splits completely in $\text{Z}(G)'$.
In the above \( \{g\} \) denotes the conjugacy class of \( g \) (and contains only one element since \( g \in Z(\text{Gal}(L/Q)) \)), \( Z(G) \) is the center of the group \( G \), and \( Z(G)' \) is the fixed field of \( Z(G) \).

The main theorem which we need is Chebotarev’s Density Theorem, 1922:

**Theorem 3.69.** Let \( N \) be a normal extension of \( \mathbb{Q} \), \( G = \text{Gal}(N/\mathbb{Q}) \), \( q \) a rational prime unramified in \( N/\mathbb{Q} \), and \( C_g \) the conjugacy class of \( g \in G \). Then the set of rational primes \( q \) for which \( \left( \frac{N/\mathbb{Q}}{q} \right) = C_g \) has natural density \( |C_g|/|G| \).

The proof of this theorem can be found in [29] or [27].

**Corollary 3.70.** The set of rational primes \( p \) that split completely in \( N \) has natural density \( 1/|G| \).

**Proof.** Let \( p \) be a rational prime that is unramified in \( N \). Since \( p \) splits completely in \( N \), by Lemma 2.5 (i) we obtain:

\[
\left( \frac{N/\mathbb{Q}}{p} \right) = \{ \text{id}_{\text{Gal}(N/\mathbb{Q})} \}
\]

Applying Theorem 2.6 we get that the set of primes \( p \) for which

\[
\left( \frac{N/\mathbb{Q}}{p} \right) = \{ \text{id}_{\text{Gal}(N/\mathbb{Q})} \}
\]

has natural density \( |\text{id}_G|/|G| \). Therefore, the set of rational primes \( p \) that split completely in \( N \) has natural density \( 1/|G| \). \( \square \)

Another result that we need is (see [31]):

**Theorem 3.71.** Let \( K \) be a number field, and let \( L \) and \( M \) be two extensions of \( K \). Then for a prime \( p \) of \( K \) we have:

(i) If \( p \) splits completely in both \( L \) and \( M \), then \( p \) splits completely in \( LM \),

(ii) If \( p \) is unramified in both \( L \) and \( M \), then \( p \) is unramified in \( LM \).
An immediate consequence of the above theorem is:

**Corollary 3.72.** Let $K$ and $L$ be number fields, $K \subset L$ and let $p$ be a prime of $K$. Then:

(i) If $p$ splits completely in $L$, then $p$ splits completely in the normal closure $M$ of $L$ over $K$,

(ii) If $p$ is unramified in $L$, then $p$ is unramified in the normal closure $M$ of $L$ over $K$.

### 3.2 The Extension

Consider the following extension:

\[
\begin{align*}
NM &= \mathbb{Q}(\sqrt{-1}, \sqrt{2}, \sqrt{\epsilon}, \sqrt{\zeta}) \\
N &= \mathbb{Q}(\sqrt{-1}, \sqrt{2}, \sqrt{\epsilon}) \\
M &= \mathbb{Q}(\zeta_{16}) \\
\mathbb{Q}(\zeta) &= \mathbb{Q}(\zeta_8) = \mathbb{Q}(\sqrt{-1}, \sqrt{2}) \\
\end{align*}
\]

Here, $\epsilon = 1 + \sqrt{2}$ is the fundamental unit of $\mathbb{Q}(\sqrt{2})$ which has norm $-1$. The Galois group $G = \text{Gal}(NM/\mathbb{Q})$ is given by the following table:
<table>
<thead>
<tr>
<th></th>
<th>$\sqrt{-1}$</th>
<th>$\sqrt{2}$</th>
<th>$\sqrt{\zeta}$</th>
<th>$\sqrt{\epsilon}$</th>
<th>Order</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\sigma_1$</td>
<td>+</td>
<td>+</td>
<td>+</td>
<td>+</td>
<td>1</td>
</tr>
<tr>
<td>$\sigma_2$</td>
<td>+</td>
<td>+</td>
<td>+</td>
<td>-</td>
<td>2</td>

<td>-</td>
<td>-</td>
<td>$-\sqrt{\epsilon}$</td>
<td>2</td>
</tr>
<tr>
<td>$\sigma_9$</td>
<td>-</td>
<td>+</td>
<td>$\sqrt{\zeta}$</td>
<td>-</td>
<td>2</td>
</tr>
<tr>
<td>$\sigma_{10}$</td>
<td>-</td>
<td>+</td>
<td>$\sqrt{\zeta}$</td>
<td>+</td>
<td>2</td>
</tr>
<tr>
<td>$\sigma_{11}$</td>
<td>-</td>
<td>+</td>
<td>$-\sqrt{\zeta}$</td>
<td>-</td>
<td>2</td>
</tr>
<tr>
<td>$\sigma_{12}$</td>
<td>-</td>
<td>+</td>
<td>$-\sqrt{\zeta}$</td>
<td>+</td>
<td>2</td>
</tr>
<tr>
<td>$\sigma_{13}$</td>
<td>-</td>
<td>-</td>
<td>$\sqrt{\zeta}$</td>
<td>$\sqrt{\epsilon}$</td>
<td>4</td>
</tr>
<tr>
<td>$\sigma_{14}$</td>
<td>-</td>
<td>-</td>
<td>$\sqrt{\zeta}$</td>
<td>$-\sqrt{\epsilon}$</td>
<td>4</td>
</tr>
<tr>
<td>$\sigma_{15}$</td>
<td>-</td>
<td>-</td>
<td>$-\sqrt{\zeta}$</td>
<td>$\sqrt{\epsilon}$</td>
<td>4</td>
</tr>
<tr>
<td>$\sigma_{16}$</td>
<td>-</td>
<td>-</td>
<td>$-\sqrt{\zeta}$</td>
<td>$-\sqrt{\epsilon}$</td>
<td>4</td>
</tr>
</tbody>
</table>

The center of this group is

$$Z(G) = \{\sigma_1, \sigma_2, \sigma_3, \sigma_4\} \cong C_2 \times C_2$$

since all the elements of $Z(G)$ have order two.

In [4], Addendum (3.7), the authors proved the following:

**Proposition 3.73.** The prime $p$ splits completely in $N$ over $\mathbb{Q}$ if and only if $p \in A^+(2)$.

Also, we recall the classic result, see [24]:

61
Proposition 3.74. The rational prime $p$ splits completely in $\mathbb{Q}((\zeta_m))$ if and only if $p \equiv 1 \pmod{m}$.

Let $\Omega = \{p \text{ prime} : p \equiv 1 \pmod{8}\}$. We have the following properties of $p \in \Omega$. By [35], Proposition 3.65, we have:

Proposition 3.75. If $p \in \Omega$ then $p$ is unramified in $N$.

Also, from [31], page 27, we obtain $\text{disc}(\mathbb{Q}((\zeta_{16})))|16^8(16)$, whence

$$\text{disc}(\mathbb{Q}((\zeta_{16})))|(2^4)^8 = 2^{32}.$$  

Recall that an odd prime $p$ is unramified in a number field $F$ if and only if $p|\text{disc}(F)$. Thus every odd rational prime $p$ is unramified in $\mathbb{Q}((\zeta_{16}))$. Let us state this:

Proposition 3.76. Every $p \in \Omega$ is unramified in $M = \mathbb{Q}((\zeta_{16}))$.

Using Propositions 3.75, 3.76 and Theorem 3.71 (ii) we obtain:

Theorem 3.77. If $p \in \Omega$ then $p$ is unramified in $NM$.

Also, from Propositions 3.73, 3.74 and Theorem 3.71 (i) we get:

Theorem 3.78. If $p \in \Omega$ then $p$ splits completely in $NM$.

Therefore we have the following splitting behavior:

Theorem 3.79. (i) $p$ splits completely in $N$ and $M$ iff $p \equiv 1 \pmod{16}$ and $p \in A^+(2)$ iff $\left(\frac{MN/Q}{p}\right) = \{\sigma_1\}$;

(ii) $p$ splits completely in $N$, yet not in $M$ iff $p \equiv 9 \pmod{16}$ and $p \in A^+(2)$ iff $\left(\frac{MN/Q}{p}\right) = \{\sigma_3\}$;

(iii) $p$ splits completely in $M$, yet not in $N$ iff $p \equiv 1 \pmod{16}$ and $p \in A^-(2)$ iff $\left(\frac{MN/Q}{p}\right) = \{\sigma_2\}$.
(iv) \( p \) splits completely neither in \( N \) nor in \( M \) iff \( p \equiv 9 \mod 16 \) and \( p \in A^{-}(2) \)

\[ \text{iff } \left( \frac{MN/Q}{p} \right) = \{\sigma_4\}. \]

**Proof.** The proof follows easily from 3.68, 3.71, 3.73, 3.74, 3.77, 3.78 since \( Z(G)' = \mathbb{Q}(\zeta) \).

Let us apply Chebotarev’s Density Theorem 3.69 to our extension \( NM/Q \). Thus we obtain:

**Theorem 3.80.** The four sets of primes \( X_1, X_2, X_3, X_4 \) have the same natural density in \( \Omega \), namely 1/4.
