INFORMATION TO USERS

This material was produced from a microfilm copy of the original document. While the most advanced technological means to photograph and reproduce this document have been used, the quality is heavily dependent upon the quality of the original submitted.

The following explanation of techniques is provided to help you understand markings or patterns which may appear on this reproduction.

1. The sign or "target" for pages apparently lacking from the document photographed is "Missing Page(s)". If it was possible to obtain the missing page(s) or section, they are spliced into the film along with adjacent pages. This may have necessitated cutting thru an image and duplicating adjacent pages to insure you complete continuity.

2. When an image on the film is obliterated with a large round black mark, it is an indication that the photographer suspected that the copy may have moved during exposure and thus cause a blurred image. You will find a good image of the page in the adjacent frame.

3. When a map, drawing or chart, etc., was part of the material being photographed the photographer followed a definite method in "sectioning" the material. It is customary to begin photoing at the upper left hand corner of a large sheet and to continue photoing from left to right in equal sections with a small overlap. If necessary, sectioning is continued again – beginning below the first row and continuing on until complete.

4. The majority of users indicate that the textual content is of greatest value, however, a somewhat higher quality reproduction could be made from "photographs" if essential to the understanding of the dissertation. Silver prints of "photographs" may be ordered at additional charge by writing the Order Department, giving the catalog number, title, author and specific pages you wish reproduced.

5. PLEASE NOTE: Some pages may have indistinct print. Filmed as received.

Let $E$ be a Helson set in a locally compact abelian group $G$ such that 1 is not in $E$. Let $F$ be a closed subset of $G$ that is disjoint from $E \cup E^{-1} \cup \{1\}$, and let $g$ be an element of $C(E)$ such that $g(x^{-1}) = \overline{g(x)}$ for $x, x^{-1}$ in $E$. Then for every $\varepsilon > 0$ there is a positive definite function $f \in C(G)$ such that $f = g$ on $E$ and $|f| < \varepsilon$ on $F$. If $h$ denotes the Helson constant of $E$ and $f_z$ denotes the Fatou-Zygmund constant of $E$, then $f_z \leq (11664)(h^{12})$. 
Let $E$ be a closed set in a locally compact abelian group $G$. $C_0(E)$ denotes the set of continuous functions on $E$ vanishing at $\infty$. A function $f$ on $E$ is hermitian if $f(x) = f(x^{-1})$ for all $x \in E \cap E^{-1}$. Let
\begin{align*}
C_0^h(E) &= \{f \in C_0(E) : f \text{ is hermitian}\} \\
A(E) &= \{f|_E : f \in A(G)\} \\
A_+(E) &= \{f|_E : f \in A(G), f \text{ is positive definite}\}
\end{align*}
$E$ is a Helson set if $C_0^h(E) = A(E)$. If $E$ is a Helson set, then
\begin{equation*}
h(E) = \sup \{\|f\|_{A(E)} : f \in C_0^h(E), \|f\|_{C_0(E)} \leq 1\}
\end{equation*}
is a finite number that is called the Helson constant of $E$. If $E$ is a Helson set, we refer to the number
\begin{equation*}
h_0(E) = \sup \{\|f\|_{A(E)} : f \in C_0^h(E), \|f\|_{C_0(E)} \leq 1\}
\end{equation*}
as the hermitian Helson constant of $E$. Helson sets in discrete $G$ are called Sidon sets.

$E$ is a Fatou-Zygmund set if $C_0^h(E) = A_+(E)$. Let
\begin{equation*}
\|f\|_{A_+(E)} = \inf \{\|g\|_A : g|_E = f, g \text{ is positive definite}\}.
\end{equation*}
$\|\|_{A_+(E)}$ is in general not a norm; for instance, $\|1\|_{A_+(G)} \neq \|-1\|_{A_+(G)}$. If $E$ is a $J-J$ set, then
\begin{equation*}
f_2(E) = \sup \{\|f\|_{A_+(E)} : f \in C_0^h(E), \|f\|_{C_0(E)} \leq 1\}
\end{equation*}
is a finite number [5, p. 94], that is called the Fatou-Zygmund constant of $E$. 

1
E is a uniform Helson set if for every closed set F disjoint from E, every \( \varphi \in C_0(E) \) and every \( \varepsilon > 0 \) there exists a \( g \in A(G) \) with
\[
g \mid_E = \varphi \\
|g| < \varepsilon \text{ on } F.
\]

E is a uniform J-2 set if for every closed set F disjoint from \( E \cup (E)^{-1} \cup \{1\} \), every \( \varphi \in C^h_0(E) \) and every \( \varepsilon > 0 \) there exists a \( g \in A_+(G) \) with
\[
g \mid_E = \varphi \\
|g| < \varepsilon \text{ on } F.
\]

S. W. Drury [1] showed that Sidon sets are uniform Helson sets. N. Th. Varopoulos [6] generalized Drury's argument to show that Helson sets are uniform Helson sets. C. S. Herz produced an alternate proof to Varopoulos' proof. Drury [2] then showed that Sidon sets are uniform J-2 sets. O. C. McGehee suggested that it might be possible by using Herz's techniques to extend Drury's argument to show that Helson sets are uniform J-2 sets, and this is what we do.

We first show:

**Theorem I.** Let \( f_2(E) = 1 \). Let F be a closed subset of G disjoint from \( E \cup E^{-1} \cup \{1\} \). Let \( \varphi \in C^h_0(E) \), \( \|\varphi\|_{C_0(E)} \leq 1 \). For every \( K > 1, \varepsilon > 0 \) there exists \( f \in A_+ C(G) \) such that:
Theorem I was proved by Varopoulos [6] for compact, totally disconnected, metrizable Kronecker sets. We prove Theorem I by making explicit an implicit proof in Herz [3]. We prove Theorem II by using Theorem I and the techniques Drury uses in showing Sidon sets are uniform \( J \)-\( J \) sets. The constants in Theorem II are the same as those that Drury obtains for the case of a Sidon set \( E \).

The outline of the paper is as follows. In Section 1 we show that in proving Theorem I or Theorem II we may suppose \( G \) is compact. We show that in proving Theorem I in the case of a compact, metrizable set we may suppose that \( E \) is also totally disconnected. Finally, we give a sufficient condition on \( E \) to yield \( f^2(E) = 1 \). Section 2 contains the Smoothing Theorem and the Transfer Lemma which are the tools for proving Theorems I, II. Theorem I is proved in Section 3, Theorem II in Section 4. We close with a few remarks in Section 5.

i) \( f = \varphi \) on \( E \)

ii) \( \|f\|_{C(F)} \leq K^2 \varepsilon \)

iii) \( \|f\|_A \leq K^2 \frac{16 \ln h_0}{\varepsilon} \)
1. **Preliminaries**

We want to show that it suffices to prove Theorems I and II in the case that \( G \) is compact. We give the reduction for Theorem I. The reduction for Theorem II is similar.

It suffices to show the reduction for an equivalent formulation of Theorem I, wherein we replace the conclusion by: For every \( \xi > 0, K > 1, \varepsilon > 0 \) there exists a \( f \in A_+(G) \) such that:

i) \( \|f - \varphi\|_{C_0(E)} < \xi \)

ii) \( \|f\|_{C(F)} \leq K^2 \varepsilon \)

iii) \( \|f\|_A \leq K^2 / \varepsilon \)

**Lemma 1.** In order to prove Theorem I, it suffices to prove it in the case when \( E \) is compact.

**Proof.** Let us suppose Theorem I is proved for the case of compact \( E \). Now let \( E \) be arbitrary. Consider the two convex subsets of \( C_0(E) \),

\[
B = \{ f \in C_0(E) : \|f - \varphi\|_{C_0(E)} < \xi \}
\]

\[
C = \{ f|_E : f \in A_+(G), \|f\|_{C(F)} \leq K^2 \varepsilon, \|f\|_A \leq K^2 / \varepsilon \}
\]

Note that \( B \) has a non-empty interior. Suppose \( B \cap C = \emptyset \), we may apply the Hahn–Banach Theorem [4, p. 157 and p. 187] to the disjoint sets \( B - \varphi, C - \varphi \). So there exists \( u \in M(E), a \in \mathbb{R} \) such that
Re $<f-\varphi,\mu> \leq a\|\mu\|$ for $f \in B$

Re $<f-\varphi,\mu> \geq a\|\mu\|$ for $f \in C$.

But Re $<f-\varphi,\mu> \leq a\|\mu\|$ for $f \in B$ implies $a \geq \xi$. We obtain that for all $f \in C$

$\xi\|\mu\| \leq \text{Re} <\varphi,\mu> \leq \int_E (f-\varphi)\,d\mu$.

Hence if $\xi' < \xi$ there exists a compactly supported $\nu$ such that $\|\nu\| \leq \|\mu\|$,

$\xi'\|\mu\| \leq \int_E (f-\varphi)\,d\nu$ for $f \in C$,

but the integral is bounded by $\|f-\varphi\|_{C(supp\,\nu)}\|\mu\|_M$. It follows that Theorem I is false for the compact set supp$(\nu)$.

**Lemma 2.** In order to prove Theorem I, it suffices to prove it in the case when $F$ is compact.

**Proof.** Let $B = \{f \in C_0(F) : \|f\|_{C_0(F)} \leq K^2 \varepsilon\}$.

$C = \{f|_F : f \in A_+(G), \|f-\varphi\|_{C_0(E)} < \xi, \|f\|_A \leq K^2 / \varepsilon\}$.

Proceed as before, applying the Hahn–Banach theorem to $B$ and $C$.

For $E$ a closed subset of $G$ let $B_{d,+}(E) = \{\hat{\mu}|_E : \mu \in M_d(G), \mu \geq 0\}$. For $f \in B_{d,+}(E)$ let

$\|f\|_{B_{d,+}(E)} = \inf\{\|\mu\|_M : \mu \in M_d(G), \mu \geq 0, \hat{\mu}|_E = f\}$. If $E$ is compact, $B_{d,+}(E) = A_+(E)$ and $\|\|_{B_{d,+}(E)} = \|\|_{A_+(E)}$.

**Lemma 3.** In order to prove Theorem I, it suffices to prove it in the case when $G$ is compact.
Proof. Supposing the theorem is proved in the case of compact $G$, consider an arbitrary $G$. Let $\theta$ be the inclusion map of $G$ into its Bohr compactification. We may suppose $E$ and $F$ are compact, so that $\theta E$ and $\theta F$ are compact. $\theta$ is symmetric; that is, $\theta(x^{-1}) = (\theta x)^{-1}$. So $\theta F$ is disjoint from $\theta E \cup (\theta E)^{-1} \cup \{1\}$.

Since $f^2(E) = 1$, $B_{d,+}(E) = A_+(E)$ and $\|B_{d,+}(E)\| = \|A_+(E)\|$ we have $f^2(\theta E) = 1$. So we have the theorem for $\theta E$ and $\theta F$. But $B_{d,+}(E \cup F) = A_+(E \cup F)$, $\|B_{d,+}(E \cup F)\| = \|A_+(E \cup F)\|$. Hence, we have the theorem for $E$ and $F$.

Lemma 4. In order to prove Theorem I in the case when $E$ is compact and metrizable, it suffices to prove it assuming that $E$ is totally disconnected.

Proof. It suffices by the argument of Lemma 1 to show that for every $K > 1$, $\epsilon > 0$, $\xi > 0$, $\mu \in M(E)$ there is a $f \in A_+(E)$ such that

i') $\left| \int f \varphi \, d\mu \right| < \xi \|\mu\|$

ii) $|f| \leq K^2 \epsilon$ on $F$

iii) $\|f\|_A \leq K^2 / \epsilon$.

Suppose Theorem I is true for totally disconnected subsets of $E$. Since $E$ is compact and metrizable, for all $\xi' > 0$ there is a $\nu \in M(E)$ such that $\text{supp } \nu$ is totally disconnected, $\text{supp } \nu \subseteq \text{supp } \mu$, and $\|\mu - \nu\|_{M(E)} < \xi'$. 

We know there is a $f \in A^+(E)$ satisfying:
\[ \left| \int f - \varphi \, d\nu \right| < \xi' \|\nu\|, \; \text{ii), } \text{iii).} \] Hence
\[ \left| \int f - \varphi \, d\mu \right| = \left| \int (f - \varphi) \, d(\nu + \mu - \nu) \right| \leq \\left( I + \frac{K^2}{\epsilon} \right) \xi' < \xi \|\mu\| \]
for correct $\xi'$.

Let $U(E) = \{ f \in C(E) : |f| = 1 \}$. Let $U^h(E)$ denote the hermitian elements of $U(E)$.

**Lemma 5.** Suppose for every $\xi > 0$, every $f \in U^h(E)$ there exists $\int \in \mathcal{G}$ such that $|f - \int| < \xi$ on $E$. Then $f_2(E) = 1$.

**Proof.** It suffices to prove this lemma under the assumption that $E$ is symmetric.

Let $A^h(E)$ denote the hermitian elements of $A(E)$. $C^h(E)$ and $A^h(E)$ are real Banach spaces under the induced norms. Let $\theta : A^h(E) \to C^h(E)$ be the natural injection.

We wish to see $\|\theta\| = 1$. Let $\theta^*$ be the dual of $\theta$.

It suffices to see $\|\theta^*\| = 1$.

We know [4, p. 179] that
\[ (C^h(E))^* = \{ \text{Re } \cdot : \mu \in M(E) \} \].

We call a measure, $\mu$, **hermitian** if $d\mu(x) = d\mu(x^{-1})$.

We denote the set of hermitian measures in $M(E)$ by $M^h(E)$. For every $\mu \in M(E)$ the hermitian measure
\[ d\nu(x) = \frac{d\mu(x) + d\mu(x^{-1})}{2} \] has the property that \( \text{Re} \langle f, \mu \rangle = \int f d\nu \) for \( f \in \mathcal{C}^h(E) \). Hence,

\[ (\mathcal{C}^h(E))^* \subseteq \{ \langle , \mu \rangle : \mu \in \mathcal{M}^h(E) \} . \]

If \( \mu \in \mathcal{M}^h(E) \), then \( \frac{d\mu}{d|\mu|} \) is hermitian a.e.

So we may write \( \frac{d\mu}{d|\mu|} = e^{ih} \) where \( h(x) = -h(x^{-1}) \mod(2\pi) \) a.e. By a modification of the proof of Lusin's theorem we may for every \( \xi > 0 \) find a continuous \( g \) such that:

\[ g(x) = -g(x^{-1}) \mod(2\pi) \] and \( g = h \) except on a set \( A \) with \( |\mu|(A) < \xi \). So for \( \mu \in \mathcal{M}^h(E) \) we have

\[ \|\mu\|_{(\mathcal{C}^h(E))^*} = \sup_{\|f\|_1 \leq 1} \left| \int f d\mu \right| = \sup_{\mathcal{C}^h(E)} \left| \int f d\mu \right| = \left( \int_{\mathcal{A}^h(E)} S d\mu \right)_{(\mathcal{A}^h(E))^*} . \]

So for every \( \xi > 0 \), every \( f \in \mathcal{C}^h(E) \) there exists \( f \in L'(\hat{\Lambda}(G)) \) satisfying: \( \|f\|_1 \leq 1 + \xi \) and \( \hat{f} = f \) on \( E \).

But \( \text{Re} f = f \) on \( E \) since \( \text{Re} f(x) = \frac{1}{2} [\hat{f}(x) + \hat{f}(x^{-1})] = \frac{1}{2} [\hat{f}(x) + \hat{f}(x^{-1})] = f(x) \).

We know there exists \( \int_{\mathcal{A}} f d\mu \) within \( \xi \) of \( -1 \) on \( E \).

Let \( f^+ \) denote the positive and negative parts of \( f \). Then \( (f^+ + \delta_{\mathcal{A}^{-1}} f^-)^\wedge \) is within \( \xi \) of \( f \) on \( E \).

So \( f^2(E) = 1 \).
2. The Drury - Herz Theorems

Given a Banach space $B$, $1 \leq p < \infty$, let $L^p(G, B)$ denote the completion of the space of continuous $B$-valued functions with compact support on $G$ for the norm $\|u\|_p = \left( \int_G \|u(x)\|^p_B \, dx \right)^{1/p}$ where $dx$ is Haar measure on $G$. The completion of this space for the supremum norm will be $C_0(G, B)$.

The Smoothing Theorem. a) Let $E$ be a compact Helson set in $G$ with Helson constant $h$, hermitian Helson constant $h_0$. Let $\theta$ be a continuous map of $E$ into a locally compact abelian group $H$. If $C$ is a compact subset of $\hat{H}$, $\delta > 0$, $K > 1$, and $\eta \in \hat{H}$, then there exists $\alpha_\eta \in L^1(\hat{G})$ such that if we let $a_x(\eta) = \hat{\alpha}_\eta(x)$ for $(x, \eta) \in G \times \hat{H}$ then:

i) $|\alpha_\eta(x) - \eta(\theta x)| < \delta$ for $(x, \eta) \in E \times C$.

ii) $\hat{\alpha}_\eta \in C_0(\hat{H}, A(G))$, $\|\hat{\alpha}_\eta\|_{C_0(\hat{H}, A(G))} \leq K^2 h^2$

iii) $a_x \in C_0(G, A(\hat{H}))$, $\|a_x\|_{C_0(G, A(\hat{H}))} \leq K^2 h^2$.

If $\theta$ is symmetric, we may replace $h$ by $h_0$ in ii), iii).

b) Suppose that $E$ is a compact symmetric Helson set and $\theta$ is symmetric. Then each $\alpha_\eta$ can be taken to be a real measure. We may write $\alpha_\eta = \alpha^{++} - \alpha^{--}$ where $\alpha^{++}, \alpha^{--}$ are nonnegative measures such that if we let
\[ a^*_\eta = a^{++}_\eta + a^{--}_\eta, \quad a^*_\eta (x) = (a^*_\eta)^\wedge (x) \text{ for } (x, \eta) \in G \times \hat{A}, \text{ then} \]

\( \ell^x \in C_0(\hat{A}, A(G)), \quad \|\ell^x\|_{C_0(\hat{A}, A(G))} \leq k^2 h^2_0. \)

\( a^*_x \in C_0(G, A(\hat{A})), \quad \|a^*_x\|_{C_0(G, A(\hat{A}))} \leq k^2 h^2_0. \)

**Proof of a)** We may find a \( k : H \to [0, 1] \) with compact symmetric support \( K \) such that \( \|k\|_{L^2(\hat{A})} \leq 1 \) and

1) \( |1 - (k * k)(\eta)| < \delta / 3 \) for \( \eta \in \mathcal{C} \).

Since \( \mathcal{C} \) is compact the set

\[ \mathcal{U} = \{ \eta \in \hat{A} : |l - \langle 0x, \eta \rangle| < \delta / 3 \text{ for all } x \in \mathcal{E} \} \]

is a neighborhood of the identity in \( \hat{A} \). Since \( K \) is compact it is covered by a finite number of translated of \( \mathcal{U} \).

\[ K \subset \bigcup_{i=1}^n \eta_i \mathcal{U}. \]

Let \( K_1 = K \cap \eta_1 \mathcal{U}, \quad K_{i+1} = (K \cap \eta_{i+1} \mathcal{U}) \setminus \bigcup_{j=1}^i K_j. \) Then

2) \( |\langle 0x, \eta_i \rangle - \langle 0x, \eta \rangle| < \delta / 3 \) for \( x \in \mathcal{E}, \eta \in K_i \).

For every \( i \) there exists \( \beta_i \in L^1(\hat{A}) \) with \( \|\beta_i\|_{L^1(\hat{A})} \leq k h \).

3) \( \hat{\beta}_i (x) = \langle 0x, \eta_i \rangle \) for \( x \in \mathcal{E} \).

Let \( b \) be the Borel measurable, \( A(G) \) valued function defined on \( \hat{A} \) by

\[ b(x, \eta) = \begin{cases} 
\beta_i(x) & \text{for } \eta \in K_i \\
0 & \text{otherwise}
\end{cases} \]

Then \( k(\eta) b(x, \eta) \in L^2(\hat{A}, A(G)) \) with norm bounded by \( k h \).
Let

5) \[ a = \kappa b * \kappa b \]

\[ a(x, \eta) \in C_0(\hat{\mathcal{H}}, \mathcal{A}(G)) \] and \[ \| a(x, \eta) \|_{C_0(\hat{\mathcal{H}}, \mathcal{A}(G))} \leq K^2 h^2 \] since

\[ \| \kappa b * \kappa b \|_{C_0(\hat{\mathcal{H}}, \mathcal{A}(G))} \leq \| \kappa b \|_{L^2(\hat{\mathcal{H}}, \mathcal{A}(G))} \| \kappa b \|_{L^2(\hat{\mathcal{H}}, \mathcal{A}(G))} \]

We let \( a_\eta \in L^1(\hat{\mathcal{G}}) \) be such that \( a_\eta = a(\cdot, \eta) \) ii) is immediate.

We wish to see iii). If \( F, G \in L^2(\mathcal{H}) \) then \( F*G \in \mathcal{A}(\hat{\mathcal{H}}) \) and \[ \| F*G \|_{\mathcal{A}(\hat{\mathcal{H}})} \leq \| F \|_{L^2(\hat{\mathcal{H}})} \| G \|_{L^2(\hat{\mathcal{H}})} \]. Hence to show iii) it suffices to show \( \kappa b \in C_0(G, L^2(\hat{\mathcal{H}})) \) and \[ \| \kappa b \|_{C_0(G, L^2(\hat{\mathcal{H}}))} \leq k h \].

This follows from the norm decreasing inclusions:

\[ L^2(\hat{\mathcal{H}}, \mathcal{A}(G)) \subseteq L^2(\hat{\mathcal{H}}, C_0(G)) \subseteq C_0(G, L^2(\hat{\mathcal{H}})) \).

We now show i). Let \( c(x, \eta) = \langle \theta x, \eta \rangle \). Then

\[ (ck) * (ck)(x, \eta) = \int_{\hat{\mathcal{H}}} \langle \theta x, \eta \rangle^{-1} \langle \theta x, \eta \rangle^{-1} \kappa(\eta_1^{-1}) \langle \theta x, \eta \rangle \langle \theta x, \eta \rangle \kappa(\eta_1) \, d\eta_1 \]

\[ = \langle \theta x, \eta \rangle (k * k)(\eta) \]

which for \( \eta \in C \) differs from \( \langle \theta x, \eta \rangle \) by no more than \( \delta / 3 \). So for \( (x, \eta) \in E \times \hat{\mathcal{H}} \),

\[ |(ck) * (ck) - (bk) * (bk)| \leq |(c-b)k * ck| + |bk * ((b-c)k| \]

\[ \leq \frac{\delta}{3} \| k \|_{L^2(\hat{\mathcal{H}})} \| ck \|_{L^2(\hat{\mathcal{H}})} + \frac{\delta}{3} \| bk \|_{L^2(\hat{\mathcal{H}})} \| k \|_{L^2(\hat{\mathcal{H}})} \leq \frac{2\delta}{3} \].
Finally, we wish to see that for the case that \( \theta \) is symmetric we may replace \( h \) by \( h_0 \) in ii), iii). If \( \theta \) is symmetric, \( \langle \partial x, \eta \rangle \) is hermitian on \( E \). So the \( \beta_1 \) of line 3) may be chosen to have \( \|\beta_1\|_1 \leq K h_0 \).

Proof of b). We note that \((\text{Re} \beta_1)^\wedge(x) = \frac{1}{2} [\beta_1(x) + \beta_1^\wedge(x)] = \frac{1}{2} [\beta_1(x) + \beta_1^\wedge(x^{-1})] = \frac{1}{2} [\eta_1(\partial x) + \eta_1((\partial x)^{-1})]

= \eta_1(\partial x) \).

Let \( \beta^+, \beta^- \) denote the positive and negative parts of \( \beta \).

Let

\[ \hat{\beta}_i(x) \text{ for } \eta \in K_i \]

6) \( b^+(x, \eta) = \)

\[ 0 \text{ otherwise} \]

\[ \hat{\beta}_i^-(x) \text{ for } \eta \in K_i \]

7) \( b^-(x, \eta) = \)

\[ 0 \text{ otherwise} \]

Let

\[ a^{++} = k b^+ \star k b^+ + k b^- \star k b^- \]

8) \( \eta \)

\[ H \]

\[ H \]

\[ a^{--} = k b^+ \star k b^- + k b^- \star k b^+ \]

9) \( \eta \)

\[ H \]

\[ H \]

The same argument that gives \( a(x, \eta) \in C_0(\wedge H, A(G)) \) will give \( a^{++}(x, \eta) \in C_0(\wedge H, A(G)) \). Let \( \eta \in C_0(\wedge H, A(G)) \) be such
that $\hat{\alpha}_{\eta}^{++} = a^{++}(\cdot, \eta)$. We see that $\alpha_{\eta} = \alpha_{\eta}^{++} - \alpha_{\eta}^{--}$.

We show iv).

$$\|\hat{\alpha}_{\eta}^{++}\|_{A(G)} =$$

$$\left\| \int (kb^+)(, \eta_{n-1}^-)(kb^+)(, \eta_1^-) + (kb^-)(, \eta_{n-1}^-)(kb^-)(, \eta_1^-) \, d\eta_1 \right\|_A$$

$$\leq \int \left( \|kb^+(, \eta_{n-1}^-)\|_A + \|kb^-(, \eta_{n-1}^-)\|_A \right) \left( \|kb^+(, \eta_1^-)\|_A + \|kb^-(, \eta_1^-)\|_A \right) \, d\eta_1.$$

But since $(kb^+)(, \eta_{n-1}^-)$ and $(kb^-)(, \eta_1^-)$ are positive definite for all $\eta_1 \in \hat{H}$ this last expression can be written

$$\int \|k(b^+ + b^-)(, \eta_{n-1}^-)\|_A \|k(b^+ + b^-)(, \eta_1^-)\|_A \, d\eta_1$$

$$\leq \|k(b^+ + b^-)\|^2_{L^2(H,A(G))} \|k(b^+ + b^-)\|^2_{L^2(H,A(G))} \leq K^2 h_0^2.$$

We show v). Let

$$\left( |\beta| \right)^{(\cdot)}(x) \text{ for } \eta \in K_i$$

10) $b^*(x, \eta) =$

$$0 \text{ otherwise}$$

Then $k(\eta) b^*(x, \eta) \in L^2(H,A(G))$ with norm bounded by $K h_0$. So $a^* = k b^* * k b^*$ $a^*_\eta = a^*(\cdot, \eta)$. We repeat the argument for iii).

**Transfer Lemma.** Let $G, H$ be locally compact abelian groups. Let $E$ be a compact subset of $G$. Let $\theta$ be a continuous map from $E$ into $H$.

a) For every $c > 0$, every $\xi > 0$ and every $f \in L^1(H, A(G))$ there exists a compact subset $C$ of $\hat{H}$ and
a \delta > 0 \text{ such that if}

\begin{align*}
    a_{t} & \in C(H, L^1(H)), \quad \|a_{t}\|_{C(H, L^1(H))} \leq c \\
    |\hat{a}_{t}(x) - a(0x)| & < \delta \text{ for } (x, \eta) \in E \times C
\end{align*}

then \( g = \int f_{\eta} \ast a_{\eta}^{-1} \, d\eta \) satisfies

\begin{enumerate}[i)]
    \item \( g \in L^1(G), \quad \|g\|_{L^1(G)} \leq c \|f\|_{L^1(G \times H)} \)
    \item \( |\hat{g}(x) - \hat{f}(x, 0x)| < \xi \text{ for } x \in E \).
\end{enumerate}

b) Let \( a_{t} \in C(H, L^1(H)) \). Define \( a_{x}(\eta) \) by

\[ a_{x}(\eta) = \hat{a}_{t}(x). \]

If \( a_{x} \in C(G, A(H)) \), \( \|a_{x}\|_{C(G, A(H))} \leq c \), then

\[ g = \int f_{\eta} \ast a_{\eta}^{-1} \, d\eta \text{ satisfies} \]

\begin{enumerate}[i)]
    \item \( |\hat{g}(x)| \leq c \sup_{\gamma \in H} |\hat{f}(x, \gamma)| \).
\end{enumerate}

Proof of a). Since \( \|g\|_{L^1(G)} \leq \)

\[
\int \|f_{\eta}\|_{L^1(G)} \|a^{-1}_{\eta}\|_{L^1(G)} \, d\eta \leq c \int \|f_{\eta}\|_{L^1(G)} \, d\eta = c \|f\|_{L^1(G \times H)}
\]

we have i).

We show ii). \( \hat{f}_{\eta} \in L^1(H, A(G)) \) and \( \|\hat{f}_{\eta}\|_{L^1(H, A(G))} = \)

\[ \|f\|_{L^1(G \times H)} \]. So there is a compact symmetric set \( C \) in

\[ H \] such that
\[ \int_{H \setminus C} \| \hat{f}_\eta \|_{A(G)} \, d\eta < \min \left( \frac{\xi}{3}, \frac{\xi}{3c} \right). \]

We write \( \hat{g}(x) = \int_{H} \hat{f}_\eta \hat{a}_{\eta^{-1}}(x) \, d\eta = \)
\[ \int_{C} \hat{f}_\eta(x) \hat{a}_{\eta^{-1}}(x) \, d\eta + \int_{H \setminus C} \hat{f}_\eta(x) \hat{a}_{\eta^{-1}}(x) \, d\eta. \]

So if we choose \( \delta = \frac{\xi}{3\|f\|_{L^1(G \times H)}} \) we will have that for \( x \in E \), \( \hat{g}(x) \) differs from \( \hat{f}(x, \theta x) \) by no more than \( \xi \).

**Proof of b).** \( \hat{g}(x) = \int_{H} \hat{f}_\eta(x) \hat{a}_{\eta^{-1}}(x) \, d\eta = \)
\[ \int_{H \setminus C} \hat{f}_\eta(x) \left( \int_{H} \hat{a}_{\eta^{-1}}(y) \, d\eta \right) \, d\eta = \]
\[ \int_{H} \hat{f}_\eta(x) \left( \int_{H} \hat{a}_{\eta^{-1}}(y) \, d\eta \right) \, d\eta = \]
\[ \int_{H \setminus C} \hat{f}_\eta(x) \left( \int_{H} \hat{a}_{\eta^{-1}}(y^{-1}) \, d\eta \right) \, d\eta = \int_{H \setminus C} \hat{f}(x, y) \hat{a}_{\eta^{-1}}(y^{-1}) \, d\eta \]
\[ \int_{H \setminus C} \hat{f}(x, y) \hat{a}_{\eta^{-1}}(y^{-1}) \, d\eta \, d\eta = \int_{H \setminus C} \hat{f}(x, y) \hat{a}_{\eta^{-1}}(y^{-1}) \, d\eta \]
\[ \sup_{y} |\hat{g}(x)| \leq c \sup_{y} |\hat{f}(x, y)|. \]

We refer to the \( \delta, c \) given by part a) of the Transfer Lemma as the \( c, \xi, f \) choice.
3. **Proof of Theorem I.**

**The Pull Back Theorem.** Let $E$ be a compact set with $f_\gamma(E) = 1$. Let $\theta : E \to H$ be continuous and symmetric. Let $\pi : H \to G$ be a continuous homomorphism such that $\pi \circ \theta = \text{id}$. Let $h \in \mathcal{A}_+(H)$. Then for every $\xi > 0$, $K > 1$, neighborhood $V$ of $1$ in $G$, there exists $g \in \mathcal{A}_+(G)$ such that:

1. $|h \circ \theta - g| < \xi$ on $E$.
2. $|g(x)| \leq K^2 \sup_{\pi y \in Vx} |h(y)|$
3. $\|g\|_A \leq K^2 \|h\|_A$.

**Proof.** Let $k' \in \mathcal{A}_+(G)$ be such that $\|k'\|_{\mathcal{A}(G)} = k'(1) = 1$, $k' = 0$ off $V^{-1}$. Then $k'(x)h(y)$ is in $\mathcal{A}_+(G \times H)$. Since $(x, y) \sim (x \pi y^{-1}, y)$ is an automorphism of $G \times H$, $f(x, y) = k'(x \pi y^{-1})h(y) \in \mathcal{A}_+(G \times H)$ $\|f\|_A \leq \|h\|_A$.

Let $\delta, c$ be the $K^2, \xi, \hat{A}$ choice. Since $h_0(E) = 1$ we may apply the Smoothing Theorem to $\delta, c, K$ to obtain $a_\eta$ that satisfy:

1. $|\hat{a}_\eta(x) - \eta(\theta x)| < \delta$ for $(x, \eta) \in E \times C$.
2. $\hat{a}_\eta \in C_0(\hat{H}, \mathcal{A}(G))$, $\|\hat{a}_\eta\|_{C_0(\hat{H}, \mathcal{A}(G))} \leq K^2$.
3. $a_x \in C_0(G, (A(\hat{H})))$, $\|a_x\|_{C_0(G, (A(\hat{H})))} \leq K^2$.

We wish to see that since $f_\gamma(E) = 1$, we may choose $a_\eta \geq 0$ for every $\eta$. We recall that $\hat{a}_\eta(x) = a(x, \eta)$.
where from line 5) \( a = kb \ast kb \). So we must check that for every \( \eta \) \( k(\eta) \geq 0 \) and \( b(x, \eta) \in A_+(G) \). But to satisfy 1) \( k \) may be chosen to be \( k = \frac{1}{(m(K))^{1/2}} \chi_K \) for a suitable compact set \( K \subset H \). Since \( f^2(E) = 1 \) and \( \theta \) is symmetric we may find \( \beta_i \in L^1(G), \| \beta_i \|_1 \leq K \), \( \beta_i \geq 0 \) such that 3) is satisfied. And from 4)

\[
\beta_i(x) \text{ for } \eta \in K_i \\
0 \text{ otherwise}
\]

Therefore \( g = \int_H f_\eta \beta_i \eta^{-1} d\eta \in A_+(G) \). \( g \) satisfies by the Transfer Lemma.

i) \( |g(x) - f(x, \theta x)| < \xi \) for \( x \in E \).

ii) \( |g(x)| \leq K^2 \sup_{y \in H} |f(x, y)| \)

iii) \( \|g\|_A \leq K^2 \|f\|_A \).

But \( f(x, \theta x) = k'(x \cdot x^{-1}) \ h(\theta x) = h(\theta x) \) for \( x \in E \), and \( \sup_{y \in H} |f(x, y)| = \sup_{\pi y \in Vx} |h(y)| \).

We will suppose in the remainder of this section that \( G \) is compact. This is possible by Lemma 3 of Section 1.

We may also assume \( \phi = 1 \), since \( f^2(E) = 1 \).

**Lemma 1.** If \( E \) is a finite set and \( f^2(E) = 1 \), then Theorem I is true for \( E \).
Proof. Write $E = E_0 \cup E' \cup e_0$ where $E_0 \cap E_0^{-1} = \emptyset$, $E_0' \subseteq E_0^{-1}$ and $e_0$ contains only elements of order $2$.

Suppose $|E_0| = r$, $|e_0| = s$. Let $E_{r+s}$ denote the canonical basis of $Z^r \times (Z_2)^s$. $E_{r+s} = \{x_1, x_2, \ldots, x_r, x_{r+1}, \ldots, x_{r+s}\}$. Let $\theta : E \rightarrow E_{r+s}$ be $1$-$1$ and symmetric. Let $\pi : Z^r \times (Z_2)^s \rightarrow G$ be the homomorphism such that $\pi \circ \theta = \text{id}$. Theorem I is true for $\theta E$ since we may choose $f$ to be transform of a suitably normalized Riesz product, $\hat{f}$

$$\hat{f} = \frac{1}{e} \left( \prod_{j=1}^{r} (1 + e(x_j + x_j^{-1})) \right) \prod_{j=n+1}^{r+s} (1 + e x_j).$$

Let $E$ be a closed subset of our compact group $G$. Let $\hat{\Gamma} = \hat{\beta} (E)$ denote the group of all continuous hermitian functions from $E$ to $T$. Give $\hat{\Gamma}$ the discrete topology, and let $\hat{\Gamma}$ be the dual group of $\hat{\Gamma}$. We define

$$\theta : E \rightarrow \hat{\Gamma}, \quad \langle \eta, \theta x \rangle = \eta (x) \text{ for } x \in E, \quad \eta \in \hat{\Gamma}.$$  

$$\hat{\pi} : \hat{\Gamma} \rightarrow \hat{\Gamma}, \quad (\hat{\pi} \hat{\delta})(x) = \langle x, \hat{\delta} \rangle \text{ for } \hat{\delta} \in \hat{\Gamma}, \quad x \in E.$$ 

$$\pi : \hat{\Gamma} \rightarrow \hat{G}, \quad \langle \hat{\gamma}, \gamma y \rangle = \langle \hat{\gamma} \hat{\gamma}, y \rangle \text{ for } y \in \hat{\Gamma}, \quad \hat{\gamma} \in \hat{\Gamma}.$$ 

Note that $\hat{\pi}$ is continuous since $\hat{\Gamma}$ is discrete.

Let $E$ be a totally disconnected closed subset of $G$. Let $j$ denote a finite collection of disjoint clopen sets with union $\Gamma$. Let $E_j$ denote the finite set of equivalence classes generated by $j$. A function $f$ is hermitian on $E_j$
if for every \( \{x_1\}, \{x_2\} \in E_j \) \( f(\{x_1\}) = \overline{f(\{x_2\})} \) whenever there exists \( x \in \{x_1\} \) such that \( x^{-1} \in \{x_2\} \). \( \Gamma(E_j) \) denotes the hermitian functions from \( E \) to \( T \). Let \( \Gamma_0(E) = \bigcup_{j \in J} \Gamma(E_j) \) where \( J \) denotes the collection of all partitions \( j \). Let \( \Gamma_0(E) \) have the discrete topology and let \( \Gamma_0(E) \) denote its dual. We define

\[
\eta_j : \Gamma_0(E) \to \Gamma(E_j), \quad \eta_j y = y|_{\Gamma(E_j)} \quad \text{for } y \in \Gamma_0(E)
\]

\[
\theta_0 : E \to \Gamma_0(E), \quad \langle \eta, \theta_0 x \rangle = \eta(x) \quad \text{for } x \in E, \quad \eta \in \Gamma_0(E)
\]

\[
\psi : \Gamma(E) \to \Gamma_0(E), \quad \langle \eta, \psi y \rangle = \langle \eta, y \rangle \quad \text{for } \eta \in \Gamma_0(E).
\]

Let \( \Delta \) denote the kernel of \( \psi \).

Lemma 2 allows the reduction to a finite set situation.

**Lemma 2.** Suppose \( E \) is a compact, totally disconnected subset of \( G \) and \( F \) is a closed subset of \( \{OE \cup (OE)^{-1} \cup \{1\}\} \cdot \Delta \) that is disjoint from \( OE \cup (OE)^{-1} \cup \{1\} \).

For every \( \varepsilon > 0 \) there exists \( k \in A_+(\Gamma(E)) \) such that

\[
|1 - k| < \varepsilon \quad \text{on } \theta E, \quad |k| < \varepsilon \quad \text{on } F \quad \text{and } \quad \|k\|_A = 1.
\]

**Proof.** The map \( (y_1, y) \mapsto y_1 \cdot y \) is 1-1 and so a homeomorphism between \( (\theta E \cup (\theta E)^{-1} \cup \{1\}) \cdot \Delta \) and \( (\theta E \cup (\theta E)^{-1} \cup \{1\}) \cdot \Delta \). So there is a closed set \( K \subset \Delta \) such that \( 1 \notin K \) and \( F \subset (\theta E \cup (\theta E)^{-1} \cup \{1\}) \cdot K \). Choose \( p \in A(\Gamma(E)) \) such that \( p(1) = 1 \), \( p = 0 \) on \( K \) and \( \|p\|_A = 1 \). For every \( \eta \in \Gamma(E) \)
there exists \( \eta_0 \in \hat{\nu}_0(E) \) such that \( |\eta - \eta_0| < \varepsilon \) on \( E \). Note this says \( |\hat{\nu}_0 \eta - 1| < \varepsilon \) on \( E \). \( \eta_0(y_1) = \eta_0(y_i) \) for \( y = \Delta \). Let \( k = \sum \hat{p}(\eta) \hat{\nu}_0 \eta \). Then
\[
|k(\theta x \cdot y) - p(y)| = |\sum \hat{p}(\eta) [\hat{\nu}_0(\theta x) \eta(\theta x) - 1] \eta(y)| < \varepsilon
\]
for \( x \in E, \ y \in \Delta \).

In the proofs of Lemma 3 and Theorem I we will use the fact that \( f^2(\theta E) = 1 \). This fact is a consequence of Lemma 5 of Section I.

**Lemma 3.** If \( E \) is compact and totally disconnected, then Theorem I is true for \( \theta E \).

**Proof.** Fix \( K > 1, \ \varepsilon > 0 \). By Lemma 2 and the fact that \( f^2(\theta E) = 1 \), there exists \( f_1 \in A_+(\Gamma(E)) \) with \( f_1 = 1 \) on \( \theta E \), \( |f_1| < 2\varepsilon \) on \( F \cap ((\theta E \cup \theta E)^{-1} \cup \{1\}) \cdot \Delta \) and \( \|f_1\|_A \leq K \). Let \( F_0 = F \cap \{y: |f_1(y)| \geq 2\varepsilon\} \). Then
\[
\psi(\theta E \cup (\theta E)^{-1} \cup \{1\}) = \theta_0 E \cup (\theta_0 E)^{-1} \cup \{1\} \text{ and } \psi F_0 \text{ are disjoint compact sets in } \Gamma(\psi(E)), \text{ Hence there exists } j \text{ such that } \pi_j(\theta_0 E \cup (\theta_0 E)^{-1} \cup \{1\}) \text{ and } \pi_j \psi F_0 \text{ are disjoint compact sets in } \Gamma(E_j). \text{ Since } \theta_0 E_j \text{ is a finite set and } f^2(\theta_0 E_j) = 1 \text{, there exists by Lemma 1 } f_0 \in A_+(\Gamma(E_j)) \text{ with } f_0 = 1 \text{ on } \theta_0 E_j, \ |f_0| \leq K \varepsilon \text{ on } \pi_j \psi F_0 \text{ and } \|f_0\|_A \leq K/\varepsilon. \text{ Let } f = f_0 \circ \pi_j \circ \psi \cdot f_1 \text{. Then } f \in A_+(\Gamma(E)) \text{, } f = 1 \text{ on } \theta E \text{, and } \|f\|_C(F) \leq \sup(K \varepsilon, K \cdot 1/\varepsilon \cdot 2\varepsilon) \leq K^2 \varepsilon \text{ for suitable } \varepsilon \text{.} \}
Proof of Theorem I. Let $V$ be a neighborhood of $1$ in $G$ such that $\overline{VF} \cap \{E \cup E^{-1} \cup \{1\}\} = \emptyset$. We may select a finite number of $\int$'s from $\hat{G}$ that separate $\overline{VF}$, $E \cup E^{-1} \cup \{1\}$; that is, if $x_1, x_2$ are from different members of this triple we have $\int$ such that $\int(x_1) \neq \int(x_2)$. Let $\hat{G}_1$ denote the group generated by these $\int$'s. Let $\hat{G}_2$ be such that $\hat{G}_1 \times \hat{G}_2 = G$. Let $G = \hat{G}_1 \times \hat{G}_2$ be the corresponding decomposition. Let $p_1 : G \to \hat{G}_1$, $p_2 : G \to \hat{G}_2$ be the projection. Let $p_1(E) = E_1$, $p_1(\overline{VF}) = F_1$. Since $G_1$ is compact and metrizable $E_1$ is metrizable. Form $\Gamma(E_1)$ and let $\theta_1 : E_1 \to \Gamma(E_1)$, $\pi_1 : \Gamma(E_1) \to G_1$ be the corresponding maps.

Since $\theta_1 E_1$ is metrizable and $f_{\theta_1 E_1} = 1$ we know by Lemma 4 of Section 1 and by Lemma 3 that there exists $f_1 \in A_+(\Gamma(E_1))$ such that:

$$f_1 = 1 \quad \text{on} \quad \theta_1 E_1$$

$$\|f_1\|_{C(\pi^{-1}_1(F_1))} \leq K^2 \epsilon$$

$$\|f_1\|_A \leq K^2 / \epsilon.$$

Let $f \in A_+(\Gamma(E_1) \times \hat{G}_2)$ be defined by:

$$f(y, x_2) = f_1(y) \quad \text{for} \quad (y, x_2) \in \Gamma(E_1) \times \hat{G}_2.$$

Then $f$ satisfies:

$$f = 1 \quad \text{on} \quad \theta_1 E_1 \times \hat{G}_2$$

$$\|f\|_{C(\pi^{-1}_1(F_1) \times \hat{G}_2)} \leq K^2 \epsilon$$

$$\|f\|_A \leq K^2 / \epsilon.$$
Let $\theta : E \to \Gamma(E_1) \times G_2$, $\pi : \Gamma(E_1) \times G_2 \to G_1 \times G_2$ be defined by: $\theta x = (\theta, p_1 x, p_2 x)$. $\pi(y, x_2) = (\pi_1 y, x_2)$. $\theta$ is symmetric and $\pi \circ \theta = \text{id}$ on $E$. We now apply the Pull Back Theorem with $H = \Gamma(E_1) \times G_2$ to complete the proof.
4. Proof of Theorem II.

We now prove Theorem II under the assumption that $G$ is compact. Form $\Gamma(E), \Gamma(E)$. Let $\theta, \pi$ be the corresponding maps. Let $gph \theta = \{(x, \theta x) : x \in E\}$. By Lemma 5 of Section 1 $f_\theta(gph \theta) = 1$. There exists $(1, \eta_-) \in \Gamma^* x \Gamma(E)$ such that $(1, \eta_-) = -1$ on $gph \theta$. Let $k^0, k^e \in \mathcal{M}_d(\Gamma^* x \Gamma(E))$ be defined by

$$k^0 = \frac{\delta(1,1) - \delta(1, (\eta_-)^{-1})}{2}, \quad k^e = \frac{\delta(1,1) + \delta(1, (\eta_-)^{-1})}{2}$$

Let $N_\theta$ be a neighborhood of $gph \theta$ for which $|k^e| < \varepsilon$. Let $V$ be a neighborhood of $1$ in $G$ such that $E \cap V = F \cap V = \emptyset$. Let $L_0 = \{(G\setminus V) \times \Gamma(E)\} \setminus N_\theta$. Let $L = L_0 \cup \{F \times \Gamma(E)\}$. Fix $K' > 1$. By Theorem I there exists $f \in A_+(G \times \Gamma(E))$ such that:

i) $f(x, \theta x) = \varphi(x)$ for $x \in E$.

ii) $\|f\|_{C(L)} \leq K'^2 \varepsilon$

iii) $\|f\|_{A(G \times \Gamma(E))} \leq \frac{K'^2}{\varepsilon}$

We use $\star$ to denote convolution on $G \times H$, $\star$ to denote convolution on $\Gamma$. Let $\sigma \in L'(\Gamma^* \times \Gamma(E))$ be such that $\sigma = f$. We make the $K'^2 h_0^2, \xi, \sigma \star k^0$ choice of $\delta > 0$ and of compact set $C \subset \Gamma(E)$. We apply the Smoothing Theorem with parameters, $C, \delta, K'$, to obtain $a_\eta, a^*, a_{\eta^-}, a_x, a^*_x$ for $x \in G, \eta \in \Gamma(E)$. Let
\[ \tau = \int_{\Gamma(E)} (\sigma \eta \star a_{\eta-1}^+ + (\sigma \delta (l, (\eta_0)_{-1})) \eta \star a_{\eta-1}^-) \, d\eta. \]

Then \( \tau \geq 0 \) and \( \|\tau\|_{L^1(G)} \leq 2/\varepsilon K' h_0^2 \). We rewrite \( \tau \)

\[ \tau = \int_{\Gamma(E)} \{ (\sigma k_0^0) \eta \star a_{\eta-1}^+ + (\sigma k^e) \eta \star a_{\eta-1}^- \} \, d\eta \]

\[ = \tau^0 + \tau^e. \]

We use the Transfer Lemma to estimate \( \hat{\tau}^0 \) at various points.

For \( x \in E \), \( \hat{\tau}^0(x) \) is within \( \delta \) of \( (\sigma k_0^0) \hat{\eta}(x, \theta x) \), and

\[ (\sigma k_0^0) \hat{\eta}(x, \theta x) = f(x, \theta x) = \varphi(x). \]

For \( x \in F \), \[ \|\hat{\tau}^0(x)\| \leq K' h_0^2 \sup_{y \in \Gamma(E)} |(f \cdot k_0^0)(x, y)| \leq K' h_0^2 \varepsilon. \]

We now estimate \( \hat{\tau}^e \).

For \( x \in E \), \[ |\hat{\tau}^e(x)| \leq K' h_0^2 \sup_{y \in \Gamma(E)} |(f \cdot k^e)(x, y)| \leq K' h_0^2 \max(\sup_{y \in N_{\eta}(x)} |(f \cdot k^e)(x, y)|, \sup_{y \in L(x)} |(f \cdot k^e)(x, y)|) \leq K' h_0^2 \varepsilon. \]

For \( x \in F \), \[ |\hat{\tau}^e(x)| \leq K' h_0^2 \sup_{y \in \Gamma(E)} |(f \cdot k^e)(x, y)| \leq K' h_0^2 \varepsilon. \]

So altogether we have

i) \[ \|\hat{\tau} - \varphi\|_{C(E)} \leq \delta + K' h_0^2 \varepsilon. \]

ii) \[ \|\hat{\tau}\|_{C(F)} \leq 2 K' h_0^2 \varepsilon. \]
iii) \[ \|\tau\|_{L^1(G)} \leq \frac{2}{\epsilon} k^{1/4} h_0^2. \]

i), ii), iii) and iteration give Theorem II.
5. Remarks.

a. Let $E$ be a Helson set and suppose $1 \not\in E$. Since every $\varphi \in C_0(E)$ may be written

$$\varphi(x) = \frac{\varphi(x) + \varphi(x^{-1})}{2} + i \frac{\varphi(x) - \varphi(x^{-1})}{2i}$$

we have $h(E) \leq \frac{1}{2} f^2(E)$. And if we use Herz's estimate that $h(E \cup E^{-1}) \leq 3^{3/2} (h(E))^3$ we obtain $f^2(E) \leq 16 \cdot 3^6 (h(E))^12$.

b. Let $E$ be a closed subset of the circle group, $T$. Let $A^+(E) = \sum_{n=0}^{\infty} |a_n e^{inx}| : \sum_{n=0}^{\infty} |a_n| < \infty \}$. $E$ is a Carleson set if $A^+(E) = C(E)$. Let

$$\|f\|_{A^+(E)} = \inf \{ \|g\|_{A^+(E)} : g \mid_E = f, g = \sum a_n e^{inx} \}.$$ 

If $E$ is a Carleson set, then

$$c(E) = \sup \{ \|f\|_{A^+(E)} : f \in C(E), \|f\|_{C(E)} \leq 1 \}$$

is a finite number, that is called the Carleson constant of $E$. I. Wik [7] showed that every Helson subset of $T$ is a Carleson set.

Let $E$ be a Helson subset of $T$ such that $1 \not\in E$. C. Graham asked whether $A^+(E) = C(E)$. The answer is yes and in fact

**Theorem.** Let $E$ be a symmetric Helson subset of $T$ such that $1 \not\in E$. Let $F$ be closed and disjoint from $E \cup \{1\}$. Let $E$ have Carleson constant $c$. Let
\[ \varphi \in C^n(E), \| \varphi \|_{C(E)} \leq 1. \] Then for every \( K > 1, \; \varepsilon > 0 \) there exists \( f \in A^*_+(E) \) such that:

i) \( f = \varphi \) on \( E \)

ii) \( |f| \leq K^2 \varepsilon \) on \( F \)

iii) \( \| f \|_A \leq K^2 16 c^4 / \varepsilon \).

**Proof.** We make the necessary modifications in the proofs of Theorems I and II. We recall from line 1) of the proof of Theorem II that the iterating function \( \tau \) is given by:

\[ \tau = \int_{\Gamma(E)} (\sigma _{\eta} \cdot \alpha ^{++}_{\eta - 1} + (\sigma _{\eta} \cdot \delta _{(1, (\eta)_-) - 1}) \eta \cdot \alpha ^{-}_{\eta - 1}) \, d\eta. \]

We must adjust \( \sigma, \alpha ^{++}, \) so that for all \( \eta : \sigma _{\eta} \geq 0, \alpha ^{++}_{\eta} \geq 0 \) and \( \sigma _{\eta} \alpha ^{++}_{\eta} \in l'(N) \) where \( N = \{0, 1, 2, \ldots \} \).

Choose \( K', \xi \) so that \( K > K' > 1, \xi > 0 \). Form \( \Gamma(E) \) and let \( \theta_1 : E \rightarrow \Gamma(E) \), \( \pi_1 : \Gamma(E) \rightarrow T \) be the corresponding maps. Let \( \text{gph} \theta_1 = \{(x, \theta, x) : x \in E\} \). Form \( \Gamma(\text{gph} \theta_1) \) and let \( \theta_2 : \text{gph} \theta_1 \rightarrow \Gamma(\text{gph} \theta_1) \), \( \pi_2 : \Gamma(\text{gph} \theta_1) \rightarrow T \times \Gamma(E) \) be the corresponding maps.

We select a neighborhood of 1, \( W = U \times V \), in \( T \times \Gamma(E) \) such that \( \overline{W}L \cap \{ \text{gph} \theta_1 \cup \{1\} \} \neq \emptyset \) where \( L \) is defined as in the Proof of Theorem II. Using Theorem I we find \( h \in A^*_+(\Gamma(\text{gph} \theta_1)) \) such that:

\[ h = 1 \text{ on } \theta_2(\text{gph} \theta_1) \]
Choose \( k_1'' \in A_+(T) \) with \( \|k_1''\|_A = k_1''(1) = 1 \) \( k_1'' = 0 \) off \( U^{-1} \). Let \( k_1' \) be a trigonometric polynomial formed from \( k_1'' \) such that \( \|k_1'\|_A = k_1'(1) = 1 \) and \( |k_1'| < \delta \) of \( U^{-1} \). Choose \( n \in \mathbb{N} \) so that \( e^{2\pi \text{int} k_1'} \) has only frequencies in \( \mathbb{N} \). Let \( k_1 = e^{2\pi \text{int} k_1'} \). Then \( k_1 \in A_+(T), \|k_1\|_A = k_1(1) = 1 \) and \( |k_1| < \delta \) of \( U^{-1} \).

Let \( k_2 \in A_+(\Gamma(E)) \) satisfy \( \|k_2\|_A = k_2(1) = 1 \)

\( k_2 = 0 \) off \( V^{-1} \). Let \( k'(x,y,y') = k_1(x) \cdot k_2(y) \) for \( x \in T, \ y \in \Gamma(E), \ y' \in \Gamma(\text{gph} \theta_1) \). For all \( y,y' \)

\( k'(\cdot,y,y') \in A_+(T) \). Let \( p_1 : T \times \Gamma(E) \to T \),

\( p_2 : T \times \Gamma(E) \to \Gamma(E) \) be the natural projections. Let

\( k(x,y,y') = k'(x \cdot p_1 \pi_2(y')^{-1}, y \cdot p_2 \pi_2(y')^{-1}, y') \).

Let \( \hat{k}, \hat{k}' \in L'(Z \times \hat{\Gamma}(E) \times \hat{\Gamma}(\text{gph} \theta_1)) \) denote the inverse transforms of \( k, k' \). Then

\[ \hat{k}'(\int, \eta, 1) \text{ if } \eta' = (\int p_1 \pi_2)^{-1} \cdot (\eta p_2 \pi_2)^{-1} \]

\[ 0 \text{ otherwise} \]

Therefore, for each \( y,y' \), \( k(\cdot,y,y') \in A_+(T) \).

So \( f_2 = k \cdot h \) satisfies for each \( y,y' \), \( f_2(\cdot,y,y') \in A_+(T) \). Let \( \sigma_2 \) be such that \( \hat{\sigma}_2 = f_2 \).

We make the \( K', \delta, \sigma_2 \) choice of \( \delta > 0 \) and of compact set \( C \subset \Gamma(\text{gph} \theta_1) \). We then apply the Smoothing
Theorem with parameters $K', \delta, C$ to obtain for every
$\eta' \in \Gamma(gph \theta_1)$ an $a_{\eta'} \in \ell'(Z \times \Gamma(E))$. Since
$f_2(p_2(gph \theta)) = 1$ we may choose $a_{\eta'}$ to satisfy:

$a_{\eta'} \geq 0 ; a_{\eta'}(\int, \eta) = 0$ unless $\int = 1$. Hence,

$$a_1 = \int_{\Gamma(gph \theta_1)} (\sigma_2)_{\eta'} \ast a_{(\eta')^{-1}} d\eta'$$

satisfies $a_1 \geq 0, a_1 \in \ell'(N \times \Gamma(E))$. Let $\hat{\sigma}_1 = f_1 \in A(T \times \Gamma(E))$. $f_1(\cdot, y) \in A^+(T)$ for all $y \in \Gamma(E)$ and

$f_1$ satisfies by the Transfer Lemma:

$$|f_1 - 1| < \varepsilon \text{ on } gph \theta_1$$
$$|f_1(x, y)| \leq K'^2 \sup_{\pi_2 y' \in W^+(x, y)} |h(y')| + \varepsilon K'^2$$
$$\|f_1\|_A \leq K'^2 \|h\|_A .$$

Since $f_2(p_2(gph \theta_1)) = 1$ we may for correct $\varepsilon$ obtain $f$ such that:

$$f(\cdot, y) \in A^+(T) \text{ for } y \in \Gamma(E) .$$

$$f = \varphi \text{ on } gph(\theta_1)$$
$$|f| \leq K^2 \varepsilon \text{ on } L$$
$$\|f\|_A \leq K^2 \|h\|_A .$$

The inverse transform of $f$ is the required $\sigma$ for the
iterating function $\tau$.

Finally, we check that we may choose for all $\eta \in \Gamma(E)$,

$a_{\eta}^{++} \geq 0$ and $a_{\eta}^{++} \in \ell'(N)$ .
We recall from the proof of the Smoothing Theorem the construction of $\alpha^{++}$. We find a function $k : \hat{\Gamma}(E) \to \mathbb{R}^+$. with compact symmetric support $K$ such that $\|k\|_2 \leq 1$ and
\[
|1 - (k * k)(\eta)| < \varepsilon_3 \quad \text{for } \eta \in C.
\]
We choose $\eta_1, \ldots, \eta_n \in \hat{\Gamma}(E)$ and write $K = \bigcup_{j=1}^{n} K_j$ where $\eta_j \in K_j$. By Wik's theorem we may find $\beta_i \in l'(N)$ such that $\|\beta_i\|_{L1} \leq KC$ and $\hat{\beta}_i(x) = \langle \theta_1 x, \eta_i \rangle$. Take
\[
\hat{\beta}_i^+, \text{ for } \eta \in K_i
\]
\[
b^+(x,\eta) =
\begin{cases}
\hat{\beta}_i^+ & \text{for } \eta \in K_i \\
0 & \text{otherwise}
\end{cases}
\]
\[
b^-(x,\eta) =
\begin{cases}
\hat{\beta}_i^- & \text{for } \eta \in K_i \\
0 & \text{otherwise}
\end{cases}
\]
where $\beta_i^+, \beta_i^-$ denote the positive and negative parts of $\beta$. Let
\[
a^{++} = k\beta^+ * k\beta^+ + k\beta^- * k\beta^-
\]
\[
a^{--} = k\beta^+ * k\beta^- + k\beta^- * k\beta^+
\]
where the convolutions are over $\hat{\Gamma}(E)$. Then $\alpha^{++}$ is defined by
\[
\hat{\alpha}^{++}(x) = a^{++}(x,\eta)
\]
\[
\hat{\alpha}^{--}(x) = a^{--}(x,\eta)
\]
Hence, for all $\eta$, $\alpha^{++}_{\eta} \geq 0$ and $\alpha^{++}_{\eta} \in l'(N)$.
