INFORMATION TO USERS

This manuscript has been reproduced from the microfilm master. UMI films the text directly from the original or copy submitted. Thus, some thesis and dissertation copies are in typewriter face, while others may be from any type of computer printer.

The quality of this reproduction is dependent upon the quality of the copy submitted. Broken or indistinct print, colored or poor quality illustrations and photographs, print bleedthrough, substandard margins, and improper alignment can adversely affect reproduction.

In the unlikely event that the author did not send UMI a complete manuscript and there are missing pages, these will be noted. Also, if unauthorized copyright material had to be removed, a note will indicate the deletion.

Oversize materials (e.g., maps, drawings, charts) are reproduced by sectioning the original, beginning at the upper left-hand corner and continuing from left to right in equal sections with small overlaps. Each original is also photographed in one exposure and is included in reduced form at the back of the book.

Photographs included in the original manuscript have been reproduced xerographically in this copy. Higher quality 6" x 9" black and white photographic prints are available for any photographs or illustrations appearing in this copy for an additional charge. Contact UMI directly to order.
On the construction and application of certain special polarizations in nilpotent Lie algebras

Acknowledgments

I thank Len Richardson for suggesting the line of inquiry which led to this dissertation, and for proffering much good advice—not always taken—and many valuable insights—not always appreciated—throughout the years of our association. He is the sine qua non of the work recorded herein.

I thank Larry Corwin and Fred Greenleaf for providing a wide and sturdy on-ramp to the nilpotent interstate; Jacek Cygan, for his time and his careful attention to detail; and Tomasz Przebinda, for a helpful observation at an opportune moment.

I thank Ray Fabec and his fellow grantees for three summers of financial support through contract number 86-LBR-016-04 of the Louisiana Education Quality Support Fund.

I thank the LSU Mathematics Department for unimpeded access to its word-processing facilities, and I thank the secretaries of that department—especially Susan Oncal, Eyvonne Coggins and Jacquie Rimes—for their many forms of assistance.

* * *

I dedicate this dissertation to my parents, James Donald Moss and Mary Vetrano Moss, who persevered in the (still unfounded) belief that their son would someday finish his education, and also to my wife, Sandra, and to my daughters, Juliette and Genevieve, who did their best to understand a husband and father who would not be understood.

This dissertation arose from efforts to prove the following conjecture, which generalizes to nilpotent Lie groups a weak form of the classical Paley-Wiener theorem for $\mathbb{R}^n$: Let $N$ be any connected, simply connected nilpotent Lie group with unitary dual $\widehat{N}$, and let $\varphi \in L^\infty_c(N)$. Suppose that there exists a subset $E \subset \widehat{N}$ of positive Plancherel measure such that $\hat{\varphi}(\pi) = 0$ for all $\pi \in E$, where $\hat{\varphi}(\pi)$ is the operator-valued Fourier transform of $\varphi$. Then $\varphi = 0$ almost everywhere on $N$. The writer has been able to prove a slightly weakened form of the conjecture for a large subclass of nilpotent Lie groups, and the conjecture itself for several interesting examples that lie outside this subclass. Chapter 3 contains these proofs, which make use of certain special polarizations (maximal subordinate subalgebras) of the Lie algebras there considered. Chapter 2 explains how to construct such polarizations in any nilpotent Lie algebra. Chapter 1 provides background for the work undertaken in Chapters 2 and 3.
§1.1 A Conjecture and its Antecedents

This dissertation arose from efforts to prove the following conjecture, which generalizes to nilpotent Lie groups a weak form of the classical Paley-Wiener theorem for IR^n:

1.1 Conjecture. Let N be any connected, simply connected nilpotent Lie group with unitary dual \( \hat{N} \), and let \( \varphi \) be a compactly supported, measurable, essentially bounded function on N (that is, \( \varphi \in L^\infty_c(N) \)). Suppose that there exists a subset \( E \subset \hat{N} \) of positive Plancherel measure such that

\[ \mathcal{F}(\pi) = 0 \quad \text{for all} \quad \pi \in E, \]

where \( \mathcal{F}(\pi) \) is the operator-valued Fourier transform of \( \varphi \). Then \( \varphi = 0 \) almost everywhere on N.

The Paley-Wiener theorem rests upon the fact that if \( \varphi \in L^\infty_c(\mathbb{R}^n) \), then \( \mathcal{F} \), the ordinary Fourier transform of \( \varphi \), has an entire extension to \( \mathbb{C}^n \). This fact permits one to conclude that \( \mathcal{F} \) is identically zero if it vanishes on a set of positive measure. But there exists no natural complex structure which corresponds to \( \hat{N} \) in the way that \( \mathbb{C}^n \) corresponds to \( \mathbb{R}^n \), and so there is a fundamental
obstacle to the proof of the proposed conjecture. Nonetheless, the writer has been able to prove a slightly weakened form of the conjecture for a large subclass of nilpotent Lie groups, and the conjecture itself for several interesting examples that lie outside this subclass. Chapter 3 contains these proofs, which make use of certain special polarizations (maximal subordinate subalgebras) of the Lie algebras there considered. Chapter 2 explains how to construct such polarizations in any nilpotent Lie algebra.

The writer first encountered a version of Conjecture 1.1 in a paper of Scott and Sitaram, "Some remarks on the Pompeiu problem for groups" [11]. Lemma 4.1 of that paper amounts to the contrapositive of Conjecture 1.1 for the \((2n+1)\)-dimensional Heisenberg group, the prototypical non-abelian nilpotent Lie group. Scott and Sitaram ask, but do not answer, the question whether their result holds for arbitrary simply connected nilpotent Lie groups.

Corwin and Greenleaf, in their paper "Fourier transforms of smooth functions on certain nilpotent Lie groups" [1], prove a theorem which implies a slightly weakened form of Conjecture 1.1 for a special subclass of nilpotent Lie groups, viz., those for which a single ideal in the corresponding Lie algebra polarizes all general position linear functionals in the dual of the algebra. Since such groups are included among those for which the writer has been able to prove the weakened form of the conjecture, more will be said about them in Chapter 3 (see §3.2).
A Lie algebra $\mathfrak{n}$ is called 'nilpotent' if its descending central series is finite, where

\[ n^{(1)} = n, \]
\[ n^{(k+1)} = [n, n^{(k)}] = \mathbb{R}\text{-span}\{[X, Y] : X \in n, Y \in n^{(k)}\}, \]

defines that series inductively. If $n^{(k+1)} = 0$, but $n^{(k)} \neq 0$, then $n$ is said to be 'k-step nilpotent', and $n^{(k)} \neq 0$ shows that the center of the algebra is non-trivial. The Birkhoff Embedding Theorem ([3], p.7) shows that every nilpotent Lie algebra is isomorphic to a subalgebra of the algebra of all $j \times j$ strictly upper triangular matrices for some $j$. The corresponding connected, simply connected nilpotent Lie group $N$, which is obtained by exponentiating the algebra $\mathfrak{n}$, may then be embedded as a subgroup of the group of upper triangular $j \times j$ matrices with 1's on the diagonal.

If $G$ is any connected Lie group with exponential map $\exp : \mathfrak{g} \to G$, the product operation

\[ X \ast Y = \log(\exp X \cdot \exp Y), \quad X, Y \in \mathfrak{g}, \]

defines an analytic function near $X = Y = 0$ which is given by a universal power series involving bracket products, or commutators, of the Lie algebra $\mathfrak{g}$. We shall use this so-called Campbell-Baker-Hausdorff (C-B-H) formula in Chapter 3. For

\[ \dagger \] For standard facts of nilpotent Lie theory, the writer relies almost entirely upon the recent text of Corwin and Greenleaf, *Representations of nilpotent Lie groups and their applications* [3].
the reader’s amusement, we give the general expression and then the first few
terms (here, \((\text{ad } A)B = [A, B]\)):

\[
X * Y = \sum_{n>0} \frac{(-1)^{n+1}}{n} \sum_{p_1 + q_1 > 0, 1 \leq i \leq n} \frac{(\sum_{i=1}^n (p_i + q_i))^{-1}}{p_1! q_1! \cdots p_n! q_n!} \\
\times (\text{ad } X)^{p_1} (\text{ad } Y)^{q_1} \cdots (\text{ad } X)^{p_n} (\text{ad } Y)^{q_n-1} Y
\]

\[
= X + Y + \frac{1}{2}[X, Y] + \frac{1}{12}[X, [X, Y]] - \frac{1}{12}[Y, [X, Y]]
\]

\[
- \frac{1}{48}[Y, [X, [X, Y]]] - \frac{1}{48}[X, [Y, [X, Y]]] + (\text{commutators in five or more terms}).
\]

(If \(q_n = 0\), the term in the sum is \(\cdots (\text{ad } X)^{p_n-1}\); if \(q_n > 1\), or if \(q_n = 0\) and \(p_n > 1\), then the term is zero.) If \(G\) is a general connected Lie group, the
C-B-H formula allows one to reconstruct the group locally (i.e., near the identity)
from knowledge of the brackets of the algebra \(g\). But if \(N\) is a connected,
simply connected nilpotent Lie group, the situation is nicer. In fact, the C-B-H
series is finite, giving global polynomial laws for the group multiplication. Also,
\(\exp : \mathfrak{n} \rightarrow N\) is an analytic diffeomorphism \(\text{onto } N\), and the C-B-H formula holds
for all \(X, Y \in \mathfrak{n}\) ([3], p. 13).

In Chapters 2 and 3 we shall take for granted an acquaintance with two
kinds of bases in a nilpotent Lie algebra \(\mathfrak{n}\). The set \(\mathcal{B} = \{X_1, \ldots, X_n\}\) is a
\textit{strong Malcev basis} for \(\mathfrak{n}\) if \(n_j = \mathbb{R}\text{-span}\{X_1, \ldots, X_j\}\) is an ideal for each
\(1 \leq j \leq n\). The set \(\mathcal{B}_w = \{X_1, \ldots, X_n\}\) is a \textit{weak Malcev basis} for \(\mathfrak{n}\) if
\(n_j = \mathbb{R}\text{-span}\{X_1, \ldots, X_j\}\) is a subalgebra for each \(1 \leq j \leq n\). Every nilpotent
Lie algebra may be given bases of either kind ([3], p. 10). As we shall see in a
few moments, strong Malcev bases play a special role in nilpotent representation
theory.
If \(x, y \in N\), then the map \(\alpha_x : y \to xyx^{-1}\) is an inner automorphism of \(N\), and its differential at the identity element, \(\text{Ad} \ x = d(\alpha_x)_{e} : n \to n\), is an automorphism of \(N\). The action \(N \times n \to n\) given by \((x, Y) \to (\text{Ad} \ x)Y\) is called the *adjoint action* of \(N\) ([3], p. 12). We have the formula

\[
\exp((\text{Ad} \ x)Y) = \alpha_x(\exp Y), \text{ for all } x \in N, \ Y \in n,
\]

from which it follows that, if \(x = \exp X\),

\[
\alpha_{\exp X}(\exp Y) = \exp(\text{Ad} \ \exp X)Y.
\]

Two other formulas that we shall find useful are

\[
(\text{Ad} \ \exp X)Y = e^{\text{ad} X}(Y) = \sum_{k=0}^{\infty} \frac{1}{k!}(\text{ad} X)^k Y, \text{ for all } X, Y \in n,
\]

(which sum, because of nilpotence, possesses only finitely many non-zero terms) and

\[
(\text{Ad} \ \exp X)Y = X \ast Y \ast (-X).
\]

If \(n^*\) denotes the linear dual of \(n\), then \(N\) acts on \(n^*\) by the contragredient of the adjoint map, the *coadjoint map* \(\text{Ad}^*:\)

\[
((\text{Ad}^* x)\ell)Y = \ell((\text{Ad} x^{-1})Y), \ Y \in n, \ \ell \in n^*, \text{ and } x \in N.
\]

Kirillov, in his seminal 1962 paper [5], revealed the importance of this map in the representation theory of nilpotent Lie groups, showing that the set \(\hat{N}\) of (equivalence classes) of irreducible unitary representations of \(N\) is naturally parametrized by the orbits of \(n^*\) under the coadjoint action of \(N\) (see §1.3 below).
Our work in Chapter 2 will use the differential of the coadjoint map at the identity in $N$. This map, denoted $\text{ad}^* : n \to \text{End}(n^*)$, is defined by

$$((\text{ad}^* X)\ell)(Y) = \ell([Y, X]) = \ell(\text{ad}(-X)Y), \quad X, Y \in n, \text{ and } \ell \in n^*,$$

as one shows by evaluating at $t = 0$ the derivative with respect to $t$ of the series

$$\text{Ad}(\exp tX) = e^{\text{ad} tX} = \sum_{k=0}^{\infty} \frac{t^k}{k!}(\text{ad} X)^k, \text{ for all } X \in n.$$ Using $\text{ad}^*$, the coadjoint action of $N$ on $n^*$ may be written, for all $X \in n$,

$$\text{Ad}^*(\exp tX)(\ell) = e^{\text{ad}^* tX}(\ell) = \sum_{k=1}^{\infty} \frac{t^k}{k!}(\text{ad}^* X)^k(\ell).$$

Again, the series has only finitely many non-zero terms in the nilpotent context.

If $\ell \in n^*$, the stabilizer subgroup of $\ell$ under the coadjoint action of $N$ is denoted by

$$R_\ell = \{x \in N : (\text{Ad}^* x)\ell = \ell\}.$$ The Lie algebra of $R_\ell$ is an important subalgebra of $n^*$, the radical of $\ell$:

$$r_\ell = \{X \in n : (\text{ad}^* X)\ell = 0\}.$$ The coadjoint orbit $O_\ell = (\text{Ad}^* N)\ell$ is homeomorphic to the homogeneous space $N/R_\ell$ and the dimension of the orbit is given by $\dim n - \dim r_\ell$ ([3], p. 26). This dimension is always even, as can be seen from the fact that $r_\ell$ is the radical of an antisymmetric bilinear form, to wit, $B_\ell : n \times n \to \mathbb{R}$, defined by

$$B_\ell(X, Y) = \ell([X, Y]), \quad X, Y \in n.$$ We shall become better acquainted with $B_\ell$ in Chapter 2, but in the meantime let us note a couple of important facts about any such form $B$ (see [3], p. 27).
If $V$ is a real vector space with an antisymmetric bilinear form $B$, its isotropic subspaces $W$ are those such that $B(w_1, w_2) = 0$ for all $w_1, w_2 \in W$. Linear algebra tells us that maximal isotropic subspaces always exist, and all have the same (even) dimension

$$\frac{1}{2} \dim(V/\text{rad } B) + \dim(\text{rad } B) = \frac{1}{2}(\dim V + \dim \text{rad } B),$$

where $\text{rad } B = \{v_1 \in V : B(v_1, v_2) = 0, \text{ for all } v_2 \in V\}$. If we let $r = \dim \text{rad } B$ and $k = \frac{1}{2} \dim(V/\text{rad } B)$, we see that $2k = n - r$ is the dimension of each of these subspaces, where $n = \dim n$.

Now if $V = n$, $\ell \in n^*$ and $B = B_\ell$, then $\text{rad } B_\ell = \tau_\ell$ and there are maximal isotropic subspaces $m_\ell$ for $B_\ell$ which are also subalgebras of $n$. Such subalgebras are said to be polarizing for $\ell$, and are usually called polarizations. They are important in the representation theory of Lie algebras and Lie groups for two reasons. In the first place, their isotropy insures that $\ell([m_\ell, m_\ell]) = 0$, so the character $\chi(\exp m_\ell) = e^{2\pi i \ell(m_\ell)}$ defines a 1-dimensional representation of the subgroup $M_\ell = \exp m_\ell$. In the second place, their maximal isotropy insures that $\chi$ induces to an irreducible unitary representation of $N$. Chapter 2 below is devoted to the construction of certain special polarizations in nilpotent Lie algebras. But before we get there, we make the briefest of sketches of the subject just broached.
§1.3 A Little Less Nilpotent Representation Theory

A unitary representation of a locally compact group $G$ is a strong operator continuous homomorphism $\pi$ of $G$ into the group $U(\mathcal{H}_\pi)$ of unitary operators on a Hilbert space $\mathcal{H}_\pi$, where the strong operator continuity means that

$$\|\pi_{g_n}\xi - \pi_g\xi\| \to 0 \text{ as } g_n \to g, \text{ for all } \xi \in \mathcal{H}_\pi.$$  

Such a representation is said to be irreducible if $\mathcal{H}_\pi$ contains no proper, closed, $\pi(G)$-invariant subspaces. The set of equivalence classes of irreducible unitary representations of $G$ is denoted by $\hat{G}$.

If one already has in hand a representation $\sigma$ of a closed subgroup $K \subseteq G$ in a Hilbert space $\mathcal{H}_\sigma$, then a representation $\pi$ of the full group $G$ in a new Hilbert space $\mathcal{H}_\pi$ may be obtained by the method of induction. The induced representation is denoted $\pi = \text{Ind}(K\uparrow G, \pi)$, and, for unimodular groups (among which are to be found all nilpotent Lie groups), the construction goes as follows (see [3], pp.39ff.). Let $\mathcal{H}_\pi$ be the Hilbert space of all Borel measurable vector-valued functions $f : G \to \mathcal{H}_\sigma$ that are

(i) covariant like $\sigma$ along $K$-cosets: $f(kg) = \sigma(k)(f(g))$,

(ii) square-summable, i.e., $\int_{K\backslash G} \|f(g)\|_{\mathcal{H}_\sigma}^2 \, dg < \infty$, where $dg$ is right-invariant measure on $K\backslash G$.

Now the map $g \to \|f(g)\|_{\mathcal{H}_\sigma}^2$ is constant on $K\backslash G$-cosets, and so too is the map $g \to \langle f_1(g), f_2(g) \rangle_{\mathcal{H}_\sigma}$. The inner product on $\mathcal{H}_\pi$ is

$$\langle f_1(g), f_2(g) \rangle_{\mathcal{H}_\pi} = \int_{K\backslash G} \langle f_1(g), f_2(g) \rangle_{\mathcal{H}_\sigma} \, dg,$$
and $\mathcal{H}_\pi$ is complete with respect to this inner product. The induced representation $\pi$ is defined by a right action of $G$ on functions $f \in \mathcal{H}_\sigma$:

$$\pi(x)f(g) = f(gx) \text{ for all } x \in G.$$ 

By the right-invariance of the measure $dg$, this action is a unitary operation. Its strong operator continuity follows from the fact that the set of functions $\mathcal{H}_{\pi,c} = \{f \in \mathcal{H}_\pi : f \text{ is continuous and supp}(f) \text{ has compact image in } K\setminus G\}$ is $L^2$-dense in $\mathcal{H}_\pi$.

To illustrate these concepts, let $K$ be any closed subgroup of $G$ such that $K\setminus G$ has an invariant measure $dg$. If the representation on $K$ is the trivial representation $\sigma = 1$ on $\mathcal{H}_\sigma = \mathbb{C}$, then the functions in $\mathcal{H}_\pi$ are scalar-valued, constant on $K\setminus G$-cosets and there is an isometry of $\mathcal{H}_\pi \cong L^2(K\setminus G, \mathbb{C})$ which carries $\pi(g)$ to the right action $R_g f(\xi) = f(\xi \cdot g)$, where $\xi = Kx \in K\setminus G$.

In particular, if $K = \{e\}$ and $dg$ is right Haar measure on $G$, then $\mathcal{H}_\pi = L^2(G)$ and $\pi = \text{Ind}(K\uparrow G, 1)$ is the right regular representation of $G$ ([3], p.40).

In the house of induced representations there are many models. Denote by $p : G \to K\setminus G$ the natural quotient map; then there always exists a Borel cross-section map $\lambda$ to $p$ such that $p \cdot \lambda = \text{id}$. If we let $\Sigma = \lambda(K\setminus G) \subseteq G$, then any $f \in \mathcal{H}_\pi$ is completely determined by its values on the transversal $\Sigma$ (because of the covariance mentioned above). The map $f \to f \cdot \lambda$, which takes functions in $\mathcal{H}_\pi$ to functions on $K\setminus G$ with values in $\mathcal{H}_\sigma$, is an isometry from $\mathcal{H}_\pi$ to $L^2(K\setminus G, \mathcal{H}_\sigma)$. Hence the unitary action of $G$ on $\mathcal{H}_\pi$ can be realized in $L^2(K\setminus G, \mathcal{H}_\sigma)$ as a cocycle action involving translation in the base.
space $K \setminus G$ and concurrent action on the values in $\mathcal{H}_\sigma$. This description, though somewhat opaque, accurately sums up what is happening when we choose a cross-section $\lambda : K \setminus G \to G$ and compute the (measurable) splitting of a typical group element $w = k(w) \cdot s(w) \in K \cdot \Sigma = K \cdot \lambda(K \setminus G)$. If $x \in G$ and $f \in \mathcal{H}_\sigma$, we have

$$\pi(g)f(x) = f(x \cdot g) = f(k(xg) \cdot s(xg)) = \sigma_{k(xg)}[f(s(xg))].$$

So, identifying $\mathcal{H}_\pi \cong L^2(K \setminus G, \mathcal{H}_\sigma)$ by sending $f \to \tilde{f}(\zeta) = f \cdot \lambda(\zeta)$, we have

$$\pi(g)\tilde{f}(\zeta) = \sigma_{k(\lambda(\zeta)g)}[\tilde{f}(\zeta \cdot g)] \quad \forall \zeta \in K \setminus G, \forall g \in G,$$

because $s(\lambda(\zeta) \cdot g) = s(K \cdot \lambda(\zeta)g) = s(\zeta \cdot g)$ is a well-defined element of the transversal $\Sigma$.

We shall use such a computation at the outset of Chapter 3 (§3.1), but of course only in the more restricted nilpotent context. Up to unitary equivalence, all irreducible representations of a nilpotent Lie group are induced from monomial representations (characters) $\chi : M \to S^1$ of subgroups $M = \exp(m)$, where $m$ is a polarization. In more detail, let $\ell \in n^*$, the linear dual of $n$. Then, as we saw in §1.2, $N$ acts on $n^*$ by the coadjoint action $\text{Ad}^*(N)$. If $\ell \in n^*$, choose a polarization $m$ for $\ell$ and let $M = \exp(m)$. Then the map $M \to S^1$ defined by

$$\chi_{\ell,M}(\exp Y) = e^{2\pi i \ell(Y)}, \quad Y \in m,$$

is a one-dimensional representation of $M$, since $\ell([m,m]) = 0$. Hence we may form the induced representation $\pi_{\ell,M} = \text{Ind}(M\uparrow G, \chi_{\ell,M})$, after the fashion explained a moment ago.

The following results of Kirillov [5] describe the unitary dual $\widehat{N}$ in terms of these induced representations (see [3], pp.45–46).
1.3.1 Theorem. Let $\ell \in \mathfrak{n}^*$. Then there exists a polarization $m$ for $\ell$, and the induced representation $\pi_{\ell,M}$ is irreducible.

1.3.2 Theorem. Let $\ell \in \mathfrak{n}^*$, and let $m, m'$ be two polarizations for $\ell$. Then $\pi_{\ell,M} \cong \pi_{\ell,M'}$. (Hence we may write $\pi_{\ell}$ for $\pi_{\ell,M}$ if we are interested only in equivalence classes of unitary representations.)

1.3.3 Theorem. Let $\pi$ be any irreducible unitary representation of $N$. Then there is an $\ell \in \mathfrak{n}^*$ such that $\pi_{\ell} \cong \pi$.

1.3.4 Theorem. Let $\ell, \ell' \in \mathfrak{n}^*$. Then $\pi_{\ell} \cong \pi_{\ell'} \iff \ell$ and $\ell'$ are in the same $\text{Ad}^*(N)$-orbit in $\mathfrak{n}^*$.

We shall not concern ourselves with the proofs of these theorems. However, it should be understood that the theorems lie at the heart of nilpotent representation theory and are taken for granted in Chapters 2 and 3 below.
§1.4 Parametrization of Coadjoint Orbits

The Kirillov theorems highlight the significance of coadjoint orbits in the representation theory of nilpotent Lie groups. But so far we have said very little about the orbits themselves. The Chevalley-Rosenlicht theorem permits us to say more. We shall state a special case—the nilpotent case—of this theorem. (For the statement and proof of a more general version of this theorem, see [3], pp. 82–83.)

1.4 Theorem (Chevalley-Rosenlicht). Let $N$ be a connected, simply connected nilpotent Lie group, and let $\text{Ad}^*(N) \ell$ denote the orbit of $\ell \in \mathfrak{n}^*$ under the coadjoint action of $N$. Then there exist vectors $X_1, \ldots, X_w \in \mathfrak{n}$, the Lie algebra of $N$, such that

$$\text{Ad}^*(N) \ell = \{ \text{Ad}^*(\exp t_1 X_1 \cdots \exp t_w X_w) \ell : t_1, \ldots, t_w \in \mathbb{R} \}.$$

The map

$$P(t_1, \ldots, t_w) = \text{Ad}^*(\exp t_1 X_1 \cdots \exp t_w X_w) \ell$$

is a diffeomorphism between $\mathbb{R}^w$ and the orbit $\text{Ad}^*(N) \ell$, and the orbit is a closed submanifold of $\mathfrak{n}^*$. In fact, let $\{ X_1^*, \ldots, X_n^* \}$ be a basis for $\mathfrak{n}^*$ such that $\mathfrak{n}_j^* = \mathbb{R}\text{-span}\{ X_{j+1}^*, \ldots, X_n^* \}$ is $\text{Ad}^*(N)$ stable for all $j$, and define polynomials $P_1, \ldots, P_n$ such that

$$\text{Ad}^*(\exp t_1 X_1 \cdots \exp t_w X_w) \ell = \sum_{j=1}^{n} P_j(t_1, \ldots, t_w) X_j^*$$

$$= P(t_1, \ldots, t_w).$$
Then there exist disjoint sets of indices $J \cup D = \{1, \ldots, n\}$ such that the set $J = \{j_1 < \cdots < j_w\}$, and the polynomial $P_j$ depends only on those variables $t_i$ with $j_i \leq j$. Moreover,

$$P_{ji} = t_i + (\text{a polynomial in } t_1, \ldots, t_{i-1}) \text{ for } 1 \leq i \leq w.$$ 

A basis $\{X_1^*, \ldots, X_n^*\}$ with the property that $\text{Ad}^*(N)(n_j^*) \subseteq n_{j+1}^*$ is called a Jordan-Hölder basis for $n^*$. Such bases always exist by the classical theorem of Engel ([3], p.4).

A question we should address before embarking on Chapter 2 is this: What is the provenance of the index set $J$? How is it determined? The answer requires a glance at part of the proof of the theorem. Let $n_j^* = \{X_{j+1}, \ldots, X_n^*\}$ and $n_n^* = (0)$; by hypothesis, $n_j^*$ is $\text{Ad}^*(N)$-stable. Let

$$n_j = \{X \in n : \text{ad}^*(X)(\ell) \in n_j^*\} = \{X \in n : \text{ad}^*(X)(\ell) = 0 \mod n_j^*\}.$$ 

Then $n_0 = n_1 = n$ (because $N$ acts unipotently\(^\dagger\)), and $n_0 \supseteq n_1 \supseteq \cdots \supseteq n_n$. What is $n_j$ algebraically? It is the annihilator of $p(\ell) \in n^*/n_j^*$ under the quotient coadjoint action of $n$ on $n^*/n_j^*$, where $p : n^* \to n^*/n_j^*$ is the natural quotient map. The set $J = \{j_1, \ldots, j_w\}$ is then the set of indices for which $n_{j-1} \supsetneq n_j$ ($j_1 \geq 2$), and so $J$ is the set of 'jump' indices, recording where the orbits of the quotient coadjoint action increase their dimension as we travel up (down?) the Jordan-Hölder series for $n^*$.

\(^\dagger\) As we saw above, every nilpotent Lie group is isomorphic to an upper triangular matrix group, each element of which has 1's on the diagonal. A 'unipotent' action, in matrix terms, is an action by such a matrix.
Recall now that a set $U \subseteq n^*$ is called Zariski-open if it is a union of sets $\{\ell \in n^* : P(\ell) \neq 0\}$, where $P$ is a polynomial. If $\{X_1^*, \ldots, X_n^*\}$ is a Jordan-Hölder basis for $n^*$ and the index sets $J$ and $D$ are determined as in the Chevalley-Rosenlicht theorem, then the set $U \subseteq n^*$ of linear functionals $\ell$ for which the dimensions of quotient coadjoint orbits in $n^*/n^*_j$ are as large as possible for each $1 \leq j \leq n$, is an $\text{Ad}^*(N)$-invariant Zariski-open set. The coadjoint orbits in $U$ are the so-called 'generic' or 'general position' orbits.

Hence we see that the definition of 'generic' is essentially basis-dependent. If we change the Jordan-Hölder basis for $n^*$, we also in general change the set of generic orbits. And since the linear dual basis of a Jordan-Hölder basis is a strong Malcev basis for $n$, the same comment applies, mutatis mutandis, to such a basis. Since our work in Chapter 2 involves fixing a strong Malcev basis for $n$ and using matrix techniques to get what we want, we thought that the basis-dependence inherent in the concept of genericity should be noted at the outset.
§2.1 A Little More Background

Let $B = \{X_1, \ldots, X_n\}$ be a strong Malcev basis for the Lie algebra $\mathfrak{n}$ of a connected, simply connected nilpotent Lie group $N$. Then the dual basis $B^* = \{X_1^*, \ldots, X_n^*\}$ is a Jordan-Hölder basis for $\mathfrak{n}^*$, the linear dual of $\mathfrak{n}$, and, as we have seen in Chapter 1, the Chevalley-Rosenlicht theorem guarantees the existence of a Zariski-open set $U \subseteq \mathfrak{n}^*$ of $N$-coadjoint orbits which are in general position with respect to the basis $B^*$ (the so-called 'generic' orbits). If $\ell = \sum_{i=1}^{n} \ell_i X_i^*$ and $O_\ell = \text{Ad}^*(N)\ell \subset U$, then $O_\ell$ has maximal dimension, which we shall say is $2k$, where $n - 2k = \dim \mathfrak{t}_\ell = r$.

The Chevalley-Rosenlicht theorem also shows that there exists a set of positive integers $J = \{j_1, \ldots, j_{2k}\}$, $2 \leq j_1 < \cdots < j_{2k} \leq n$, such that every generic orbit $O_\ell$ lies over the $2k$-dimensional subspace $W_J = \mathbb{R}\text{-span}\{X_{j_1}^*, \ldots, X_{j_{2k}}^*\}$. We call $J$ the set of orbit (or jump) indices determined by the basis $B^*$. If $D = \{d_1, \ldots, d_r\}$, $1 = d_1 < \cdots < d_r \leq n$, where $J \cup D = \{1, \ldots, n\}$ and $J \cap D = \emptyset$, then the $r$-dimensional subspace $W_D = \mathbb{R}\text{-span}\{X_{d_1}^*, \ldots, X_{d_r}^*\}$ intersects $U$ in a cross-section of the set of generic orbits and $\hat{\mathcal{N}}_{g,p} \cong \mathcal{W} = U \cap W_D$, where $\hat{\mathcal{N}}_{g,p}$ denotes the representations in $\hat{\mathcal{N}}$ in general position. For this reason
we call \( D \) the set of parameter (or dual) indices. If \( \ell \in \mathcal{W} \), we shall write
\[
\ell = \sum_{i=1}^{r} \ell_{d_i} X_{d_i}^*,
\]
and call \( \ell \) a 'generic parametrizing' functional (or 'generic orbit representative'). The components \( \ell_{d_1}, \ldots, \ell_{d_r} \) will be called the 'generic parametrizing components' of \( \ell \) (of course these components must satisfy certain conditions, about which more anon). If \( dm_*^r \) denotes \( r \)-dimensional Lebesgue measure on \( W_D \), then the measure
\[
dR = |\text{Pfaffian}(\ell)| \, dm_*^r
\]
on the set \( \mathcal{W} \) of generic orbit representatives may be transferred to a Borel measure \( d\rho \) on \( \hat{\mathcal{N}} \) with support \( \hat{\mathcal{N}}_{g.p.} \). This is the Plancherel measure for \( \hat{\mathcal{N}} \).

\section{A Structure Theorem for Nilpotent Lie Algebras}

We wish to show that there exists in \( \mathfrak{n}^* \) a subset \( \mathcal{W}_S \subseteq \mathcal{W} \) consisting of what we shall call 'strongly generic parametrizing functionals'. The set \( \mathcal{W}_S \) has the following properties:

1. For each \( \ell \in \mathcal{W}_S \), there exists a weak Malcev basis
\[
B_w(\ell) = \{X_1, \ldots, X_c, Y_{m_1}, Y_{m_2}, \ldots, Y_{m_p}, X_{e_1}, \ldots, X_{e_k}\}
\]
for \( \mathfrak{n} \) such that:

   (a) \( c + 1 = m_1 < \ldots < m_p \leq n \) and \( c + 2 \leq e_1 < \ldots < e_k \leq n \);

   (b) The vectors \( X_1, \ldots, X_c, Y_{m_1} \) and \( X_{e_1}, \ldots, X_{e_k} \) are fixed elements of the original strong Malcev basis \( B \) which do not depend on \( \ell \);

   (c) \( \mathfrak{z}(\mathfrak{n}) = \mathbb{R} \cdot \text{span}\{X_1, \ldots, X_c\} \) is the center of \( \mathfrak{n} \);

   (d) \( Y_{m_1} = X_{c+1} \);
(e) Each vector $Y_{m_t}^\ell$, $2 \leq t \leq p$, has the form

$$Y_{m_t}^\ell = X_{m_t} + \sum_{e_j < m_t} c_{m_t,e_j}(\ell) X_{e_j},$$

where $X_{m_t}$ is a fixed element of the basis $\mathbf{B}$ and the coefficients $c_{m_t,e_j}(\ell)$ are rational nonsingular functions which depend only on the parametrizing components $\ell_{d_1}, \ldots, \ell_{d_s}$ of $\ell$ such that $d_s < m_t$;

(f) $m_\ell = \mathbb{R} \text{span}\{X_1, \ldots, X_c, Y_{m_1, \ell}, Y_{m_2, \ell}, \ldots, Y_{m_p, \ell}\}$ is a polarizing subalgebra for $\ell$ through which the basis $\mathbf{B}_w(\ell)$ passes (a 'special' polarization).

(2) The $r$-dimensional Lebesgue measure of $\mathcal{W} \sim \mathcal{W}_S$ is zero, so $\mathcal{W}_S$ contains almost all generic parametrizing functionals, and the set of representations $\pi \in \hat{N}_{g,p}$ which are not induced from characters $\chi_\ell$ for $\ell \in \mathcal{W}_S$ also has Plancherel measure zero.

In the applications to follow in Chapter 3, we shall employ the standard methods of Mackey [6] and Kirillov [5] to construct a (Schrödinger) model for the representation $\pi_\ell$ corresponding to $\ell \in \mathcal{W}_S$. In this model, $\pi_\ell$ will act in $L^2(\mathbb{R} \text{span}\{X_{e_1}, \ldots, X_{e_k}\})$, where $L^2$ is formed with respect to the ordinary Euclidean measure $dx_1 \cdots dx_k$ in $\mathbb{R}^k$. Thus the Hilbert space $\mathcal{H}_{\pi_\ell}$ for $\pi_\ell$ will be fixed for all $\ell \in \mathcal{W}_S$. Since we shall wish to decompose Haar measure $d\nu$ on $N$ (Euclidean measure $dn$ on $n$) into a Cartesian product of the measure $dx_1 \cdots dx_k$ with a suitable Haar measure $dm(\ell)$ on $M_\ell = \exp m_\ell$, we shall take $dm(\ell)$ to be the measure on $M_\ell$ obtained by projection onto the coordinate hyperplane spanned by the set of vectors

$$\mathbf{B} \sim \{X_{e_1}, \ldots, X_{e_k}\} = \{X_1, \ldots, X_c, X_{m_1}, \ldots, X_{m_p}\}$$
from the original strong Malcev basis $B$. This hyperplane will be equipped with
its ordinary $(n - k)$-dimensional Euclidean measure

$$dm_{n-k} = dx_1 \cdots dx_c \, dx_{m_1} \cdots dx_{m_p}.$$  

Our choice of a single family of rationally varying (indeed, rotating) polarizations
for strongly generic representations enables us thereby to fix one modelling space
shared by all strongly generic $\pi_\epsilon$, and to specify a useful Haar measure $dm(\ell)$ for
each $M_\ell$ corresponding to $\pi_\epsilon$.

§ 2.3 Theorems of Kirillov and of Vergne

As we shall see, a single method of construction suffices to determine the set $W_S$, the
special polarizations $m_\epsilon$, and the special bases $B_w(\ell)$. This method rests
squarely upon the shoulders of the following two theorems (see [3], pp.29–30):

2.3.1 Theorem (Kirillov). Let $n_0$ be a codimension 1 subalgebra in a nilpotent
Lie algebra $n$. Let $\ell \in n^*$ and $\ell^0 = \ell|_{n_0}$. Then if $r_\ell$ denotes the radical of
$\ell$, there are two mutually exclusive possibilities.

Case 1, characterized by any of the following equivalent properties:

(i) \( r_\ell \subseteq n_0 \)

(ii) \( r_\ell \subseteq r_{\ell^0} \)

(iii) \( r_\ell \) has codimension 1 in $r_{\ell^0}$. In this case, any subalgebra which
polarizes $\ell^0$ also polarizes $\ell$.  

Case 2, characterized by any of the following equivalent properties:

(i) \( \tau_{\ell} \not\subseteq n_0 \)

(ii) \( \tau_{\ell^0} \subseteq \tau_{\ell} \)

(iii) \( \tau_{\ell^0} \) has codimension 1 in \( \tau_{\ell} \). In this case, if \( m \) is a polarizing subalgebra for \( \ell \), then \( m_0 = m \cap n_0 \) is a polarizing subalgebra for \( \ell^0 \); also, \( m_0 \) has codimension 1 in \( m \) and \( m = m_0 + \tau_{\ell} \).

2.3.2 Theorem (Vergne). Let \( B = \{X_1, \ldots, X_n\} \) be a strong Malcev basis for a nilpotent Lie algebra \( n \), and let \( n_j = \text{IR-span}\{X_1, \ldots, X_j\} \). Let \( \ell \in n^* \) and let \( \ell^j = \ell|_{n_j} \). Then

\[
m_{\ell} = \sum_{j=1}^{n} \tau_{\ell^j}
\]

is a polarizing subalgebra for \( \ell \), where

\[
\tau_{\ell^i} = \{X \in n_j : \text{ad}^*(X)\ell^j = 0\}
\]

is the radical of \( \ell^j \).

We shall use these two theorems as follows. Suppose that \( \ell^j = \ell|_{n_j} \) is the restriction to \( n_j \) of a generic functional in \( U \), and suppose also that \( \ell^j \in W_D \), the set of parametrizing functionals. Then if

\[
m_{\ell^j-1} = \sum_{i=1}^{j-1} \tau_{\ell^i}
\]

has already been contructed, Theorem 2.3.1 tells us that
(1) either \( m_{\ell i} = m_{\ell i-1} \), which is the case if \( r_{\ell i} \subseteq r_{\ell i-1} \);
(2) or else \( m_{\ell i} = m_{\ell i-1} + r_{\ell i} \), which is the case if \( r_{\ell i-1} \subseteq r_{\ell i} \).

Since \( m_{\ell 1} = r_{\ell 1} = \mathbb{R}X_1 \) always, it is clear that our task at the \( j \)-th stage of the construction of \( m_{\ell} \) consists, at worst, in finding a vector \( Y_j \) such that

\[
r_{\ell i} = r_{\ell i-1} + \mathbb{R}Y_j.\]

For then

\[
m_{\ell i} = m_{\ell i-1} + r_{\ell i}
= m_{\ell i-1} + r_{\ell i-1} + \mathbb{R}Y_j
= m_{\ell i-1} + \mathbb{R}Y_j,
\]
since \( r_{\ell i-1} \subseteq m_{\ell i-1} \). After \( n \) stages, Theorem 2.3.2 tells us that \( m_{\ell n} = m_{\ell} \) is a polarizing subalgebra for \( \ell \).

§ 2.4 Some Matrix Notation

Since the strong Malcev basis \( B \) for \( n \) has been fixed for the duration (as is necessary for any definition of orbits in general position), we shall work with matrix versions of several objects. We take a moment to fix some notation. Recall that \( B_\ell : n \times n \rightarrow \mathbb{R} \) denotes the antisymmetric bilinear form given by

\[
B_\ell(W_1, W_2) = \ell([W_1, W_2]) \quad \text{for} \ \ell \in n^* \ \text{and} \ W_1, W_2 \in n.
\]

Let \([B_\ell]\) denote the matrix of \( B_\ell \) with respect to the basis \( B \), and let \([B_\ell]_{j \times j}\) denote the upper left-hand \((j \times j)\)-block of \([B_\ell]\). Let \([X]\) denote the vector \( X \in n \) written as a column vector with respect to \( B \) (so \([X] \in \mathbb{R}^n\), and
let \( [X]_{j \times 1} \) denote the column vector consisting of the top \( j \) entries of \( [X] \) (so \( [X]_{j \times 1} \in \mathbb{R}^j \)). Recall that the radical of \( \ell^j = \ell \mid_{n_j} \) is

\[
\tau_{\ell^j} = \{ X \in n_j : \ell^j([X,Y]) = 0 \text{ for all } Y \in n_j \} \\
= \{ X \in n_j : \text{ad}^*(X)\ell^j = 0 \}.
\]

In matrix notation we may write, for \( X \in n_j \),

\[
\text{ad}^*(X)\ell^j = [B_{\ell^j}]_{j \times j} [X]_{j \times 1},
\]

where juxtaposition signifies matrix multiplication. So

\[
\tau_{\ell^j} \cong \{ [X]_{j \times 1} \in \mathbb{R}^j : [B_{\ell^j}]_{j \times j} [X]_{j \times 1} = 0 \}.
\]

§2.5 Outline of the Construction Method

Suppose now that we have constructed \( m_{\ell^{i-1}} \) and are seeking to construct \( m_{\ell^i} \). We know that if \( \tau_{\ell^i} \subset \tau_{\ell^{i-1}} \) we may simply set \( m_{\ell^i} = m_{\ell^{i-1}} \), while if \( \tau_{\ell^{i-1}} \subset \tau_{\ell^i} \) we may set \( m_{\ell^i} = m_{\ell^{i-1}} + \mathbb{R}Y_j \). Thus for \( 1 \leq j \leq n \) we first need a way of deciding whether \( \tau_{\ell^i} \subset \tau_{\ell^{i-1}} \) or \( \tau_{\ell^{i-1}} \subset \tau_{\ell^i} \), and then, if the latter inclusion holds, we need a way of finding a vector \( Y_j \) with the requisite property (of course, \( Y_j \) will not be unique and will, in general, depend on \( \ell \)).

Consider the linear system

\[
(*) \quad [B_{\ell^j}]_{j \times j} [X]_{j \times 1} = \begin{bmatrix} 0 \\ \vdots \\ 0 \end{bmatrix}_{j \times 1}.
\]

As we have just seen, the set of all vectors \( [X]_{j \times 1} \) satisfying this system is (isomorphic to) \( \tau_{\ell^i} \). And as we shall see in §2.9, there exists a well-defined
procedure for row- and column-reducing the matrix \([B_{\ell}]_{j \times j}\) which always produces either an antisymmetric matrix with a bottom (j-th) row of zeros, or else an antisymmetric matrix with a single non-zero entry on its bottom row, which entry is also the only non-zero entry in its column.

Suppose, on the one hand, that the bottom row of the reduced matrix \([B_{\ell}]_{j \times j}\) consists of zeros. Then, by antisymmetry, the right-hand (j-th) column also consists of zeros, from which it follows that any solution to (*) is unconstrained in the variable \(x_j\). Hence \(r_{\ell j} \not\subseteq n_{j-1} = \mathbb{R}\text{-span}\{X_1, \ldots, X_{j-1}\}\), and Case 2 of Theorem 2.3.1 implies that \(r_{\ell j-1} \subseteq r_{\ell j}\). On the other hand, suppose that the bottom row of the reduced matrix \([B_{\ell}]_{j \times j}\) contains a single non-zero entry on its bottom row, which entry has only zeros above it. Then, by antisymmetry, the right-hand column contains only a single non-zero entry, which entry has only zeros to its left, and it follows that any solution to (*) must satisfy \(x_j = 0\). Hence \(r_{\ell j} \subseteq n_{j-1}\), and Case 1 of Theorem 2.3.1 implies that \(r_{\ell j} \subseteq r_{\ell j-1}\).

At the j-th stage of our construction process, then, it appears that we must accomplish three things:

(1) insure that \(\ell^j\) is the restriction to \(n_j\) of a linear functional \(\ell \in \mathcal{W}\), where \(\mathcal{W} = U \cap W_D\);

(2) insure that \([B_{\ell}]_{j \times j}\) is fully row- and column-reduced (in a manner to be specified below);

(3) construct \(m_{\ell j}\), which may involve finding an (in general) \(\ell\)-dependent vector \(Y_j\) which satisfies the equation \(m_{\ell j} = m_{\ell j-1} + \mathbb{R}Y_j\).

These three tasks may in fact be carried out simultaneously, as we now proceed to show. Keep in mind that our aim is to produce the set \(\mathcal{W}_S\) and, for each
\( \ell \in \mathcal{W}_S \), a special polarization \( m_\ell \) and a special weak Malcev basis \( B_w(\ell) \) which passes through \( m_\ell \).

§ 2.6 Illustration of the Construction Method

We may at our pleasure fix a strong Malcev basis \( B \) for \( n \) which passes through the center \( z = \mathbb{R}\text{-span}\{X_1, \ldots, X_c\} \). Since \( B_\ell(X_i, X_j) = 0 \) for \( 1 \leq i, j \leq c + 1 \), the top \( c \) rows and the left-hand \( c \) columns of \( [B_\ell] \) consist of zeros, and so it is obvious that the upper left-hand \((c + 1) \times (c + 1)\) block of \([B_\ell]\) is the \((c + 1) \times (c + 1)\) zero matrix for all \( \ell \in n^* \). Indeed,

\[
[B_\ell] = \begin{bmatrix}
0 & \cdots & 0 & 0 & \cdots & \cdots & 0 & 0 \\
\vdots & \ddots & \vdots & \vdots & \ddots & \ddots & \vdots & \vdots \\
0 & \cdots & 0 & 0 & \cdots & \cdots & 0 & 0 \\
0 & \cdots & 0 & b_{c+1,c+2} & \cdots & \cdots & b_{c+1,n} & \\
0 & \cdots & 0 & b_{c+2,c+1} & 0 & \cdots & \cdots & \cdots \\
\vdots & \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \vdots \\
\vdots & \vdots & \vdots & \vdots & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & \cdots & \cdots & \cdots & 0 & b_{n-1,n} \\
0 & \cdots & 0 & b_{n,c+1} & \cdots & \cdots & b_{n,n-1} & 0
\end{bmatrix}_{n \times n},
\]

where the entry \( b_{i,j} \) is, in general, a polynomial in the first \( i - 1 \) components of \( \ell \). Hence \( r_{\ell,c+1} = \mathbb{R}\text{-span}\{X_1, \ldots, X_{c+1}\} \), and we may always set \( m_{\ell,c+1} = r_{\ell,c+1} \).

Setting \( Y_{m_1} = X_{c+1} \), we have the first \( c + 1 \) vectors of all of the bases \( B_w(\ell) \) that we are seeking to construct. We note for the record that \( Y_{m_1} \) is the first “internal
orbit vector"\(^\dagger\) in the bases and we set \(i_1 = m_1\) to signify this fact. (It will always be the case that \(i_1 = m_1 = c + 1\) and that the first "jump" index is \(j_1 = i_1\).) In addition, we are free to set \(\ell_{i_1} = 0\) since components in orbit directions are not parametrizing components (there will be \(2k\) parametrization conditions before we are done). By the way, for obvious reasons we shall henceforward gently abuse notation by regarding \([B_\ell]\) as the \((n - c) \times (n - c)\) matrix obtained by deleting the top rows and and left-hand columns of zeros. Thus, we shall write (usually without comment)

\[
[B_\ell] = \begin{bmatrix}
0 & b_{c+1,c+2} & \cdots & \cdots & \cdots & b_{c+1,n} \\
b_{c+2,c+1} & 0 & \cdots & \cdots & \cdots \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
\vdots & \vdots & \ddots & 0 & b_{n-1,n} \\
b_{n,c+1} & \cdots & \cdots & b_{n,n-1} & 0 \\
\end{bmatrix}_{n-c \times n-c}
\]

or, remembering that \(B_\ell\) is an antisymmetric bilinear form,

\(^\dagger\) As we have already mentioned, generic \(N\)-coadjoint orbits lie suspended over the subspace \(W_D = \text{IR-span}\{X_{j_1}^*, \ldots, X_{j_{2k}}^*\}\), where \(J = \{j_1 < \cdots < j_{2k}\}\) is the set of orbit indices. We are calling a vector in the basis \(B\) an "internal orbit vector" if it is indexed by some \(j_i \in J\) and if it is also in \(\mathfrak{m}_\ell\). Similarly, a vector in \(B\) will be called an "external orbit vector" if it is indexed by some \(j_i \in J\) and if it lies outside \(\mathfrak{m}_\ell\). We let \(J_I = \{i_1, \ldots, i_{c}\}\) and \(J_E = \{e_1, \ldots, e_{k}\}\) denote, respectively, the sets of internal and external orbit indices.
Suppose, for illustrative purposes, that the entry $b_{c+1,c+2}$ is not identically zero (and so is a non-trivial polynomial in the components $\ell_1, \ldots, \ell_c$ of $\ell$). Then there are two alternatives:

(1) we set $b_{c+1,c+2} = 0$, in which case

$$\mathfrak{r}_{\ell c+2} = \mathfrak{r}_{\ell c+1} + \mathbb{R}X_{c+2} \subset \mathfrak{r}_{\ell c+1},$$

and we may proceed as in the $c+1$ case;

(2) we set $b_{c+1,c+2} \neq 0$ (that is, we disregard functionals $\ell$ for which $b_{c+1,c+2} = 0$), in which case

$$\mathfrak{r}_{\ell c+2} = \mathfrak{r}_{\ell c} \subset \mathfrak{r}_{\ell c+1},$$

and we may set $\mathfrak{m}_{\ell c+2} = \mathfrak{m}_{\ell c+1}$, then set $X_{\ell 1} = X_{c+2}$ (the first "external orbit vector"), and then move on.

The problem with alternative (1) is that it can prevent a functional from being generic. To see this, recall from Chapter 1 that a linear functional $\ell \in n^*$ is called ‘generic’ if, speaking in matrix terms now, the rank of $[B_{\ell}]_{j \times n}$ is as large as possible for each $1 \leq j \leq n$ (see also [3], p.86). Equivalently, $\ell$ is generic if the dimension of $\mathfrak{a}_j$, the annihilator of $[B_{\ell}]_{j \times n}$, is as small as possible for each $j = 1, \ldots, n$, where
\[ a_j = \{ X \in n : \text{ad}^\ast(X)\ell^j = 0 \} \]
\[ = \{ [X] \in \mathbb{R}^n : [B_\ell]_{j \times n} [X] = 0 \}. \]

Insuring the genericity of a functional \( \ell \) requires us (in general) to prohibit certain polynomials in the components of \( \ell \) from being zero, not set them equal to zero. In short, alternative (1) is sure to get us into trouble eventually. \(^\dagger\)

It would seem, then, that we are encouraged by the facts of the matter to embrace alternative (2). If \( b_{c+1,c+2} \) is not identically zero and we then prohibit it from being zero, we do in fact make the ranks of the rectangular matrices \([B_\ell]_{(c+1) \times n}\) and \([B_\ell]_{(c+2) \times n}\) as large as possible (that is, 1 and 2, respectively). So we are on our way to genericity for \( \ell \). And we see that \( i_1 = c+1 \) and \( e_1 = c+2 \) are internal and external orbit indices, respectively, and we may set \( \ell_{i_1} = \ell_{e_1} = 0 \), since, again, components in orbit directions are not parametrizing components.

But what do we do about \( r_{\ell,c+3} \)? Now we are confronted with the matrix

\[
[B_\ell]_{(c+3) \times (c+3)} = \begin{bmatrix}
0 & b_{c+1,c+2} & b_{c+1,c+3} \\
-b_{c+1,c+2} & 0 & b_{c+2,c+3} \\
-b_{c+1,c+3} & -b_{c+2,c+3} & 0
\end{bmatrix}.
\]

\(^\dagger\) If an example is wanted, one need look only as far as the 3-dimensional Heisenberg group \( H_1 \). If its Lie algebra \( \mathfrak{h}_1 \) is viewed as \( \mathbb{R}\text{-span}\{X_1, X_2, X_3\} \), where \([X_3, X_2] = X_1\), then for \( \ell \in \mathfrak{h}_1^* \) we have

\[
[B_\ell] = \begin{bmatrix}
0 & 0 & 0 \\
0 & 0 & \ell_1 \\
0 & -\ell_1 & 0
\end{bmatrix}.
\]

Setting \( \ell_1 = 0 \) forces the rank of \([B_\ell]\) to be 0, whereas setting \( \ell_1 \neq 0 \) forces the rank of \([B_\ell]\) to be 2. Of course, for \( \mathfrak{h}_1 \) the set \( U \) of generic functionals consists precisely of those \( \ell \) such that \( \ell_1 \neq 0 \).
We must decide whether $r_{\ell c+2} \subset r_{\ell c+3}$ or $r_{\ell c+3} \subset r_{\ell c+2}$. And if the former inclusion holds, we must find a vector $Y_{c+3}$ such that

$$m_{\ell c+3} = m_{\ell c+2} + \text{IR} Y_{c+3}.$$

Recall that the solution set of the linear system

\[
(* \quad [B_{\ell}]_{(c+3) \times (c+3)} [X]_{(c+3) \times 1} = \begin{bmatrix} 0 \\ \vdots \\ 0 \end{bmatrix} \] \]

is algebraically isomorphic to $r_{\ell c+3}$. To solve the system, it suffices to row-reduce $[B_{\ell}]_{(c+3) \times (c+3)}$. Under the continuing temporary hypothesis that $b_{c+1,c+2} \neq 0$, we find that this matrix reduces to

$$
\begin{bmatrix}
0 & b_{c+1,c+2} & b_{c+1,c+3} \\
-b_{c+1,c+2} & 0 & b_{c+2,c+3} \\
0 & 0 & 0
\end{bmatrix},
$$

where we have

(1) added $(b_{c+2,c+3} \times \text{row 1})$ to $(b_{c+1,c+2} \times \text{row 3})$, and

(2) added $(-b_{c+1,c+3} \times \text{row 2})$ to $(b_{c+1,c+2} \times \text{row 3})$.

Now since $[B_{\ell}]$ and $[B_{\ell}]_{(c+3) \times (c+3)}$ are antisymmetric matrices, after row-reducing we should also column-reduce to restore the antisymmetry. If we do this now to the above row-reduced version of $[B_{\ell}]_{(c+3) \times (c+3)}$, we get the antisymmetric matrix
\[
\begin{bmatrix}
0 & b_{c+1,c+2} & 0 \\
-b_{c+1,c+2} & 0 & 0 \\
0 & 0 & 0
\end{bmatrix}.
\]

The right-hand column of zeros tells us that any solution to the system (*) is unconstrained in the variable \(x_{c+3}\), whence \(r_{\ell c+3} \not\subseteq n_{c+2}\). It then follows from Case 2 of Theorem 2.3.1 that \(r_{\ell c+2} \subset r_{\ell c+3}\), and so

\[
m_{\ell c+3} = m_{\ell c+2} + \mathbb{R}Y_{c+3}
\]

for some \(\ell\)-dependent vector \(Y_{c+3}\).

§ 2.7 Lessons of the Illustration

A few comments are in order here. In the first place, we row-reduced as if the entries of \([B_{\ell}]\) were scalars in a ring (rather than a field) for reasons of typographical convenience. In the second place, since \([B_{\ell}]\) and \([B_{\ell}(c+3) \times (c+3)]\) are antisymmetric matrices, after row-reducing we also column-reduced to restore the antisymmetry. In the third place, we did not interchange rows in the reduction process (in an attempt to produce a so-called “echelon form”). The reason for this is simple: \(n\) is more than just a vector space—it is an algebra. Indeed, it is an algebra in which a strong Malcev basis has been fixed. To interchange two rows in \([B_{\ell}]\) is to interchange two vectors in \(B\), and so to run the risk of losing the ‘strength’ of the basis, which consists in the fact that \(\mathbb{R}\)-span\{\(X_1, \ldots, X_j\)\} is an ideal for \(1 \leq j \leq n\). Since that strength will be used later on (in § 2.10, to be exact), row interchanges must be forbidden. In the fourth place, the reduction of \([B_{\ell}(c+3) \times (c+3)]\) employed the antisymmetric pair \(b_{c+1,c+2}\) and \(-b_{c+1,c+2}\), and relied upon the hypothesis that \(b_{c+1,c+2} \neq 0\). It is clear that to determine
the containment relations of \( r_{\ell c+2} \) and \( r_{\ell c+3} \) only one reduction by one antisymmetric pair was necessary. This phenomenon is general: to determine the containment relations of \( r_{\ell i} \) and \( r_{\ell i+1} \), at most one reduction by one antisymmetric pair is necessary (of course, no reduction may be necessary or even possible). Each such reduction will require us to prohibit a non-trivial polynomial in (some of) the components of \( \ell \) from being zero (these prohibitions will be called 'strong genericity conditions', for reasons to be explained). So, summing up the lessons of this special case, we shall in the future always

1. reduce as if working over a ring rather than a field;
2. antisymmetrize after each reduction;
3. refrain from interchanging rows during reduction;
4. reduce (when necessary) by using antisymmetric pairs which have been subjected to a strong genericity condition, drawing conclusions as each pair is used.

§2.8 A Less Than Rare Device

There is still another problem that we need to address before discussing the general case: how do we find the vector \( Y_{c+3} \)? In fact, we need a device to produce this vector for us, and we find this device in a special kind of augmented matrix. Let

\[
[A_{\ell}]_{(c+3) \times (c+4)} = \begin{bmatrix}
[B_{\ell}]_{(c+3) \times (c+3)} & | & X_{c+1} \\
0 & b_{c+1,c+2} & b_{c+1,c+3} & | & X_{c+1} \\
-b_{c+1,c+2} & 0 & b_{c+2,c+3} & | & X_{c+2} \\
-b_{c+1,c+3} & -b_{c+2,c+3} & 0 & | & X_{c+3}
\end{bmatrix},
\]
where the entries in the right-hand column—the ‘bookkeeping’ column, as we shall call it—are not scalars, but rather vectors from $B$, the fixed strong Malcev basis for $n$. If we now row-reduce and antisymmetrize $[B_\ell]_{(c+3) \times (c+3)}$ as before, the bookkeeping column records the $\ell$-dependent basis changes wrought thereby. Indeed, the following matrix results:

$$
\begin{bmatrix}
0 & b_{c+1,c+2} & 0 & | & X_{c+1} \\
-b_{c+1,c+2} & 0 & 0 & | & X_{c+2} \\
0 & 0 & 0 & | & \tilde{X}_{c+3}
\end{bmatrix},
$$

where

$$
\tilde{X}_{c+3} = b_{c+1,c+2} X_{c+3} - b_{c+1,c+3} X_{c+2} + b_{c+2,c+3} X_{c+1}.
$$

This vector has the property that $r_{\ell,c+3} = r_{\ell,c+2} + \tilde{X}_{c+3}$, where $r_{\ell,c+2}$ is, of course, just the center $j$ of $n$. Hence, $m_{\ell,c+3} = m_{\ell,c+2} + \tilde{X}_{c+3}$, and we see that this vector is a fine choice for the vector $Y_{c+3}$ that we seek. However, we can do better than this. Since $X_{c+1} \in m_{\ell,c+2}$ (as seen above), we may set

$$
m_{\ell,c+3} = m_{\ell,c+2} + \tilde{X}_{c+3},
$$

where

$$
\tilde{X}_{c+3} = b_{c+1,c+2} X_{c+3} - b_{c+1,c+3} X_{c+2}.
$$

Now, $i_2 = c + 3$ is the second internal orbit index, and $\tilde{X}_{c+3}$ depends only upon $\ell$, $X_{i_2}$, and $X_{\ell_1} = X_{c+2}$, the first external orbit vector. If we set $m_2 = i_2$, we may write

$$
Y_{m_2}^\ell = \frac{1}{b_{c+1,c+2}} \tilde{X}_{c+3}
= X_{m_2} + c_{m_2,\ell_1}(\ell) X_{\ell_1},
$$
where
\[ c_{m_2,e_1}(\ell) = \frac{-b_{c+1,c+3}}{b_{c+1,c+2}} \]
is a rational nonsingular function of those \( \ell \in \mathbb{N}^* \) satisfying the strong genericity condition \( b_{c+1,c+2} \neq 0 \) and the parametrization conditions \( \ell_{i_1} = \ell_{e_1} = 0 \). The vector \( Y_{m_2}^{\ell} \) is perhaps the best choice for a vector which spans \( m_{\ell c+3} \sim m_{\ell c+2} \).

If we compare this vector to item (1e) in §2.2 above, we see that its form is exactly as advertised.

The vector \( \tilde{X}_{m_2} = \tilde{X}_{c+3} \) spans that part of the radical \( t_{\ell c+3} \) which is not already contained in \( t_{\ell c+2} \) (i.e., \( t_{\ell c+3} \sim t_{\ell c+2} \)), while the vector \( \tilde{X}_{m_2} = \tilde{X}_{c+3} \) spans that part of the radical \( t_{\ell c+3} \) which is not already contained in \( m_{\ell c+2} \) (i.e., \( m_{\ell c+3} \sim m_{\ell c+2} \)). Since it is only the latter vector which interests us, let us adapt our augmented matrix device to produce such a vector. Indeed, all we need do is stipulate that once a bookkeeping column entry has been found to be an element of some \( m_{\ell i} \), that entry is immediately replaced by zero in the bookkeeping column. This has the effect of eliminating linear redundancies among the basis elements of \( m_{\ell} \). In the present example, the vector \( X_{c+1} \) should have been replaced by zero as soon as it was seen to be an element of \( m_{\ell c+1} \) (and so of \( m_{\ell} \)). That is, instead of looking like this:

\[
\begin{bmatrix}
0 & b_{c+1,c+2} & b_{c+1,c+3} & | & X_{c+1} \\
-b_{c+1,c+2} & 0 & b_{c+2,c+3} & | & X_{c+2} \\
-b_{c+1,c+3} & -b_{c+2,c+3} & 0 & | & X_{c+3}
\end{bmatrix},
\]

the augmented matrix \( [A_{\ell}]_{(c+3) \times (c+4)} \) should have looked like this:

\[
\begin{bmatrix}
0 & b_{c+1,c+2} & b_{c+1,c+3} & | & 0 \\
-b_{c+1,c+2} & 0 & b_{c+2,c+3} & | & X_{c+2} \\
-b_{c+1,c+3} & -b_{c+2,c+3} & 0 & | & X_{c+3}
\end{bmatrix}.
\]
Then, reducing as we did before, we would have arrived at the matrix

\[
\begin{bmatrix}
0 & b_{c+1,c+2} & 0 & 0 \\
-b_{c+1,c+2} & 0 & 0 & X_{c+2} \\
0 & 0 & 0 & 1X_{c+3}
\end{bmatrix},
\]

where we have replaced $\tilde{X}_{c+3}$ by $^1X_{c+3}$ (the pre-superscript notation is obviously preferable to the tilde-stacking notation for showing how many reductions have been performed). But remember: $^1X_{c+3}$ does not span $r_{\ell,c+3} \sim r_{\ell,c+2}$, but only $m_{\ell,c+3} \sim m_{\ell,c+2}$. Fortunately, this is enough for our purposes.

§2.9 The General Construction

We are ready now to generalize the concepts and techniques developed over the last few pages under the temporary hypothesis that $b_{c+1,c+2} \neq 0$. Suppose that $\ell \in \mathfrak{n}^*$ is perfectly arbitrary. Since $\mathfrak{z}(n) = \mathbb{R} \text{-span}\{X_1, \ldots, X_c\}$, we have $r_{\ell,c} = \mathfrak{z}(n)$ and we may set $m_{\ell,c} = r_{\ell,c} = \mathfrak{z}(n)$. So our work begins at row $c+1$ of $[B_\ell]$, or rather at row $c+1$ of the augmented matrix

\[
[A_\ell] =
\begin{bmatrix}
0 & b_{c+1,c+2} & \cdots & \cdots & \cdots & b_{c+1,n} & X_{c+1} \\
-b_{c+1,c+2} & 0 & \cdots & \cdots & \cdots & 0 & X_{c+2} \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\
\vdots & \vdots & \cdots & \cdots & \cdots & \cdots & \vdots \\
-b_{c+1,n} & \cdots & \cdots & \cdots & 0 & b_{n-1,n} & X_{n-1} \\
-b_{c+1,n} & \cdots & \cdots & \cdots & 0 & b_{n-1,n} & X_n
\end{bmatrix}.
\]

Note that $[A_\ell]$ has not as yet undergone any reductions by antisymmetric pairs. This will soon change.

Now because the basis vector $X_{c+1} \in \mathcal{B}$ is non-central, row $c+1$ of $[A_\ell]$ contains at least one entry which is a non-trivial polynomial in the components...
\( \ell_1, \ldots, \ell_c \) of \( \ell^{c+1} = \ell \big|_{n_{c+1}} \) (this entry need not be \( b_{c+1,c+2} \), as we assumed above). Let \( L_{c+1} \) denote the column in which the leftmost such entry is to be found, and let \( b_{c+1,L_{c+1}} \) denote the entry itself. Restrict \( \ell \) by prohibiting \( b_{c+1,L_{c+1}} \) from being zero; that is, set

\[(SGC \ 1) \quad b_{c+1,L_{c+1}} \neq 0.\]

This is the first of our strong genericity conditions (note that it insures that the rank of \( [B\ell]_{(c+1) \times n} \) is 1, which is as large as possible). We use the adjective ‘strong’ to point up the possibility that there exist generic functionals in \( n^* \) for which \( b_{c+1,L_{c+1}} = 0 \), and so we are beginning here to pick out a subset of the full set of generic functionals in \( n^* \).\(^\dagger\)

Since row \( c + 1 \) contains a non-zero entry, \( c + 1 \in J \), the set of orbit indices. Also, \( L_{c+1} \in J \) since \( b_{L_{c+1},c+1} \neq 0 \). In fact, \( c + 1 = i_1 \) is the first internal orbit index, while \( L_{c+1} \) is an external orbit index (though we cannot as yet say which one it is). We restrict \( \ell \) further by requiring that

\[(PC \ 1) \quad \ell_{c+1} = \ell_{L_{c+1}} = 0.\]

This is our first parametrization condition. The two conditions \((SGC \ 1) \) and \((PC \ 1) \) together insure that \( \ell^{i_1} \) is, as desired, the restriction to \( n_{c+1} \) of a functional \( \ell \in W = U \cap W_D \)

Next we note that \( L_{c+1} > c + 1 \), so the entry \( b_{c+1,L_{c+1}} \) is above the diagonal of \( [A_\ell] \) (of course, we are abusing language here just a bit since \( [A_\ell] \) is not a

\(^\dagger\) The algebra labelled \( g_{6,17} \) in Nielsen ([7], p.84) provides an example in which the set of strongly generic parametrizing functionals is a proper subset of the set of generic parametrizing functionals. The non-zero brackets are generated by \( [X_6,X_5] = X_1, [X_6,X_3] = X_2, [X_5,X_4] = X_2, [X_4,X_3] = X_1 \). It is easy to see that the SGPF's satisfy the condition \( \ell_1 (\ell_1^2 + \ell_2^2) \neq 0 \), while the GPF's satisfy the weaker condition \( (\ell_1^2 + \ell_2^2) \neq 0 \).
square matrix). Thus row \( c+1 \) consists of zeros out to column \( c+1 \), indeed out to column \( L_{c+1} - 1 \). This means, as we know, that \( r_{\epsilon^c} \subset r_{\epsilon^{c+1}} \), and so we may set \( m_{\epsilon^{c+1}} = m_{\epsilon^c} + R X_{c+1} \), where \( X_{c+1} \) is the bookkeeping column entry on row \( c+1 \). It is worth remarking that the entries on row \( c+1 \) between column \( L_{c+1} \) and the bookkeeping column have no bearing on the question whether or not \( X_{c+1} \) spans \( m_{\epsilon^{c+1}} \sim m_{\epsilon^c} \). This is because \( B^* = \{X_1^*, \ldots, X_n^*\} \) is a Jordan-Hölder basis for \( n^* \). Finally, we set \( Y_{m_1} = X_{c+1} \) and replace \( X_{c+1} \) by zero in the bookkeeping column.

We are ready now to row-reduce and antisymmetrize \([A_\ell]\) (rather than an upper left-hand block thereof). Since \( b_{c+1, L_{c+1}} \neq 0 \) and since it is both the leftmost non-zero entry on row \( c+1 \) and the topmost non-zero entry in column \( L_{c+1} \), we may use it to sweep out column \( L_{c+1} \). If \( c+2 \leq j \leq n \), and \( j \neq L_{c+1} \),

1. we multiply row \( j \) of \([A_\ell]\) by \( b_{c+1, L_{c+1}} \);

2. then we add \((-b_{j, L_{c+1}} \times \text{row } c+1)\) to row \( j \), producing a new row \( j \) whose \((j, L_{c+1})\)-entry is zero.

Now \( b_{c+1, L_{c+1}} \) is the only non-zero entry in column \( L_{c+1} \). (Of course, if it already was the only such entry, then no row operations were necessary.)

By the antisymmetry of \([B_j]\), we have that \( b_{L_{c+1}, c+1} = -b_{c+1, L_{c+1}} \), and so \( b_{L_{c+1}, c+1} \) is both the topmost non-zero entry in column \( c+1 \) and the leftmost non-zero entry on row \( L_{c+1} \). Thus we may use \( b_{L_{c+1}, c+1} \) to sweep out column \( c+1 \). For each \( L_{c+1} < j \leq n \), add \((b_{j, c+1} \times \text{row } L_{c+1})\) to row \( j \), producing a new row \( j \) whose \((j, c+1)\)-entry is zero. Now \( b_{L_{c+1}, c+1} \) is the only non-zero entry in column \( c+1 \). (Again, if it already was the only such entry, then no row operations were necessary).
Having row-reduced \([A_\ell]\) (perhaps vacuously) using \(b_{c+1,L_{c+1}}\) and its antisymmetric partner \(b_{L_{c+1},c+1}\), we now column-reduce by the same pair. We call the resulting antisymmetrized matrix \(1[A_\ell]\) (antisymmetrized modulo the bookkeeping column, of course). This matrix has the form

\[
1[A_\ell] = \begin{bmatrix}
1[B_\ell] \\
\vdots \\
1[X_{n-1}] \\
1[X_n]
\end{bmatrix},
\]

where for \(c + 2 \leq j \leq n\),

\[
1X_j = \begin{cases} 
X_j, & \text{if } j = L_{c+1}; \\
 b_{c+1,L_{c+1}} X_j + b_{j,c+1} X_{L_{c+1}}, & \text{otherwise}.
\end{cases}
\]

In this expression for \(1X_j\), the coefficient \(b_{j,c+1}\) may well be zero, but the coefficient \(b_{c+1,L_{c+1}}\) is never zero because of \((SGC \ 1)\). As a consequence, the vectors \(1X_j\) always have a non-zero component in the direction of \(X_j\), and further reduction of \(1[B_\ell]\) will not alter this fact. Indeed, if \(s\) reductions have been performed on \([A_\ell]\), producing the matrix \(s[A_\ell]\), then the bookkeeping column entry \(sX_j\), if it has not already been zeroed out, will always have a non-zero component in the direction of \(X_j\) (because the coefficient of \(X_j\) in \(sX_j\) will be a product of polynomials in the parametrizing components of \(\ell\), each factor of which has been restricted to be non-zero by a strong genericity condition). For this reason, we may speak of \(sX_j\) as being an “orbit” vector if \(j \in J\), the set of
orbit indices for the basis $B$. By this we shall mean simply that the bookkeeping column vector $sX_j$ has a non-zero component in the direction of $X_j$.\footnote{Note that none of the vectors $s^{-1}X_j$ depends on the first $c+1$ vectors $X_1, \ldots, X_{c+1}$ of the basis $B$ because these vectors were replaced by zeros in the bookkeeping column before reduction was begun.}

Since $2k$ is the maximal rank of $[B_\ell]$, $k$ reductions are required in order to reduce $[A_\ell]$ completely (some or all of which may be vacuous). Suppose that $[A_\ell]$ has been reduced $s$ times, where $1 \leq s \leq k$. Then for $c+2 \leq j \leq n$, the bookkeeping column entry on row $j$ of $s[A_\ell]$ has the form

$$sX_j = \begin{cases} 
  s^{-1}X_j & \text{if } j = L_{i_s}; \\
  (s^{-1}b_{i_s, L_{i_s}})(s^{-1}X_j) + (s^{-1}b_{i_s, L_{i_s}})(s^{-1}X_{L_{i_s}}) & \text{otherwise.}
\end{cases}$$

Here, the index $i_s$ denotes the $s$-th internal orbit direction, and

$$(s^{-1}b_{i_s, L_{i_s}})(s^{-1}X_j) = (s^{-1}b_{i_s, L_{i_s}}) \times \cdots \times (1b_{i_2, L_{i_2}})(b_{i_1, L_{i_1}})X_j,$$

where $b_{i_1, L_{i_1}}, \ldots, s^{-1}b_{i_s, L_{i_s}}$ are the polynomials (in the parametrizing components of $\ell$) which have been prohibited from being zero by the first $s$ (not necessarily distinct) strong genericity conditions.

The general stage of the construction process may now be described. For each $c+2 \leq j \leq n$, there are exactly three cases to consider. We shall examine each case under the supposition that $[A_\ell]$ has been reduced $s$ times, where $1 \leq s \leq k$.

\textbf{Case 1} Suppose row $j$ consists entirely of zeros. Then $j \in D$, the set of parameter indices, and $r_{\ell j-1} \subset r_{\ell j}$ (by Theorem 2.3.1). Hence if

$$m_{\ell j-1} = \text{IR-span}\{X_1, \ldots, X_c, X_{m_1}^{\ell}, X_{m_2}^{\ell}, \ldots, X_{m_{\ell-1}}^{\ell}\},$$
where $m_1 = c+1$ and $X_{m_1}, X_{m_2}^\ell, \ldots, X_{m_{t-1}}^\ell$ are the former bookkeeping column entries on rows $m_1, \ldots, m_{t-1}$ of $s[A]$, then we may set

$$m_{\ell i} = m_{\ell i-1} + \mathbb{R} X_{m_t}^\ell,$$

where $X_{m_t}^\ell = sX_j$ is the current bookkeeping column entry on row $j$ of $s[A]$. We then replace $X_{m_t}^\ell$ by zero in the bookkeeping column. However, because $\ell_j$ is a parametrizing component, we do not set it equal to zero. Since row $j$ consists of zeros, no reduction of $s[A]$ is possible, so if $j < n$, we proceed to row $j + 1$; otherwise, we are done.

**Case 2** Suppose row $j$ contains an entry $s_{b_{i,j}}$, which is the leftmost non-trivial polynomial in the parametrizing components of $\ell^j$, and which also lies above the diagonal of $s[B]$, that is, $L_j > j$. (Note that this implies that $j < n = \text{dim } n$.) Then only zeros appear on that part of row $j$ which is below the diagonal, and so $r_{\ell j-1} \subset r_{\ell j}$ (by Theorem 2.3.1). If, as in Case 1,

$$m_{\ell j-1} = \mathbb{R}\text{-span}\{X_1, \ldots, X_c, X_{m_1}, X_{m_2}^\ell, \ldots, X_{m_{t-1}}^\ell\},$$

where $m_1 = c+1$ and $X_{m_1}, X_{m_2}^\ell, \ldots, X_{m_{t-1}}^\ell$ are the former bookkeeping column entries on rows $m_1, \ldots, m_{t-1}$ of $s[A]$, then we may again set

$$m_{\ell j} = m_{\ell j-1} + \mathbb{R} X_{m_t}^\ell,$$

where $X_{m_t}^\ell = sX_j$ is the current bookkeeping column entry on row $j$ of $s[A]$. Since $X_{m_t}^\ell \in m_{\ell j}$, $m_t$ is an internal orbit index, so we set $i_{s+1} = m_t = j$. Then
we replace \( X_j \) by zero in the bookkeeping column and establish our \((s+1)\)-th parametrization condition

\[(PC \ s+1) \quad \ell_{i_{s+1}} = \ell_{L_{i_{s+1}}} = 0,\]

and our \((s+1)\)-th strong genericity condition

\[(SGC \ s+1) \quad s_{b_{j,L_j}} = s_{b_{i_{s+1},L_{i_{s+1}}}} \neq 0.\]

(Even if this entry has appeared in a prior SGC, there is no harm in its appearing in another). Next, we produce the \((s+1)\)-times reduced matrix \( s+1[A_{\ell}] \) by row- and column-reducing \( s[A_{\ell}] \) using \( s_{b_{i_{s+1},L_{i_{s+1}}}} \) and its antisymmetric partner. Finally, we proceed to row \( j+1 \).

**Case 3** Suppose row \( j \) contains an entry \( s_{b_{j,L_j}} \) which is the leftmost non-trivial polynomial in the parametrizing components of \( \ell^j \), and which is below the diagonal of \( s[B_{\ell}] \), that is, \( L_j < j \). Then this entry has already appeared in a strong genericity condition, and so it is prohibited from being zero for the functionals \( \ell \) that we are considering. As a consequence, the bottom row of the \( s \)-times reduced upper left-hand block matrix \( s[B_{\ell}]_{j \times j} \) does not consist of zeros, and so \( r_{\ell;i} \subset r_{\ell;j-1} \) (by Theorem 2.3.1), and we may set

\[ m_{\ell;i} = m_{\ell;i-1}. \]

This implies that \( X_j \), the bookkeeping column entry on row \( j \) of \( s[A_{\ell}] \), is not an element of any of the polarizations \( m_{\ell;i} \), nor will it be an element of the polarizations \( m_{\ell} \) when their construction is complete. But—and here is the important part—if \( X_j \not\in m_{\ell} \), then neither is \( X_j \), the \( j \)-th vector in the original
strong Malcev basis $B$ for $n$. We already know the reason: by construction, $sX_j$ is a linear combination of the vector $X_j$ and certain other vectors $X_i$ with $i < j$, and the coefficient of $X_j$ in this linear combination is guaranteed by our previous strong genericity conditions never to be zero for the functionals $\ell$ that we are considering. What all of this means is that the vector $X_j$ is external to all of the polarizations that we are constructing.

Now $X_j$ may or may not be the first such external orbit vector from the basis $B$ found during the construction process. Indeed, suppose that $X_j$ is the $w$-th one found, where $1 \leq w \leq k$. Then we set $X_{e_w} = X_j$ and we call $X_{e_w}$ the $w$-th external orbit vector. As noted above, $e_w \in J_E$. Since the entry $s_{e_w, L_{e_w}}$ is below the diagonal, it will have already been subject to a strong genericity condition and been used to sweep out column $L_{e_w}$ and row $e_w$. Hence no reduction of $s[A_\ell]$ is necessary. Also, $\ell$ will have already been subject to the parametrization condition $\ell_{e_w} = 0$. So if $j < n$, we proceed to row $j + 1$; otherwise, we are done.

§2.10 Results of the General Construction

When the construction process just outlined is completed (i.e., when $j = n$), we find ourselves in the possession of $n$ vectors

$$X_1, \ldots, X_c, X_{m_1}, X_{m_2}, \ldots, X_{m_p}, X_{e_1}, \ldots, X_{e_k}$$

such that the entire Lie algebra

$$n = \mathbb{R}\text{-span}\{X_1, \ldots, X_c, X_{m_1}, X_{m_2}, \ldots, X_{m_p}, X_{e_1}, \ldots, X_{e_k}\},$$
and the subspace
\[ m_\ell = \mathbb{R}\text{-span}\{X_1, \ldots, X_c, X_{m_1}, X_{m_2}, \ldots, X_{m_\ell}\} \]
is a polarizing subalgebra for the linear functional \( \ell \in \mathfrak{n}^* \), provided \( \ell \) satisfies the strong genericity condition
\[
(SGC*) \quad \left( k-1b_{i_k,L_{i_k}} \right) \times \cdots \times \left( 1b_{i_2,L_{i_2}} \right) \left( b_{i_1,L_{i_1}} \right) \neq 0
\]
and the parametrization conditions
\[
(PC*) \quad \ell_{i_1} = \cdots = \ell_{i_k} = \ell_{e_1} = \cdots = \ell_{e_k} = 0.
\]

If we call the set of all such functionals \( \mathcal{W}_S \), then (SGC*) assures us that \( \mathcal{W}_S \subseteq U \), the set of generic functionals with respect to the basis \( B \), and (PC*) assures us that \( \mathcal{W}_S \subseteq \mathcal{W}_D \). Hence, \( \mathcal{W}_S \subseteq \mathcal{W} = U \cap \mathcal{W}_D \), as desired. The set \( \mathcal{W}_S \) consists, of course, of our strongly generic parametrizing functionals. A typical member of \( \mathcal{W}_S \) has the form
\[
\ell = \ell_{d_1} X_{d_1}^* + \cdots + \ell_{d_r} X_{d_r}^*,
\]
where \( 1 = d_1 < \cdots < d_r \leq n \). Recall that these indices comprise the set \( D \) of dual (or parameter) indices. It is important to note that it is only the components \( \ell_{d_1}, \ldots, \ell_{d_r} \) that appear in the condition (SGC*).

If we now divide each vector \( X_{m_\ell}^\ell \) by the coefficient of its \( X_{m_\ell} \) term, which coefficient is guaranteed by (SGC*) to be non-zero for \( \ell \in \mathcal{W}_S \), we find that
\[
X_{m_\ell}^\ell = X_{m_\ell} + \sum_{e_j < m_\ell} c_{m_\ell,e_j}(\ell) X_{e_j},
\]
where \( X_{m_t} \) is a fixed element of \( B \) and the coefficients \( c_{m_t,e_j}(\ell) \) are rational nonsingular functions which depend only on the parametrizing components \( \ell_{d_1}, \ldots, \ell_{d_s} \) of \( \ell \) such that \( d_s < m_t \). The reason for this last remark is clear: rows \( 1, \ldots, m_t \) of the matrix \([B_\ell]\) contain entries which depend, at most, on the components \( \ell_1, \ldots, \ell_c, \ell_{m_1}, \ldots, \ell_{m_{s-1}} \) of \( \ell \), and so the bookkeeping column entry on row \( m_t \) which gave rise to the vector \( Y_{m_t}^\ell \) can itself depend at most on the same components (because of its mode of construction). It is important to observe, too, that the summation in the above expression for \( Y_{m_t}^\ell \) involves (besides \( X_{m_t} \) itself), only fixed, non-\( \ell \)-dependent external orbit vectors \( X_{e_j} \), with \( e_j < m_t \). Again, this is due to our construction process, which involves zeroing out bookkeeping column vectors found to be elements of \( m_\ell \).

Why is the set \( \{X_1, \ldots, X_c, Y_{m_1}, Y_{m_2}^\ell, \ldots, Y_{m_p}^\ell, X_{e_1}, \ldots, X_{e_k}\} \) a weak Malcev basis for \( n \)? In the first place, for each \( 1 \leq t \leq p \), the subspace

\[
\mathbb{R} \text{-span}\{X_1, \ldots, X_c, Y_{m_1}, Y_{m_2}^\ell, \ldots, Y_{m_t}^\ell\}
\]

is a subalgebra by construction. And in the second place,

\[
[Y_{m_t}^\ell, X_{e_i}] = [X_{m_t} + \sum_{e_j < m_t} c_{m_t,e_j}(\ell) X_{e_j}, X_{e_i}]
\]

\[
= [X_{m_t}, X_{e_i}] + \sum_{e_j < m_t} c_{m_t,e_j}(\ell) [X_{e_j}, X_{e_i}],
\]

which vector is contained in

\[
m_\ell \oplus \mathbb{R} \text{-span}\{X_{e_1}, \ldots, X_{e_{i-1}}\}
\]

because \( B \) is a strong Malcev basis for \( n \). Hence for each \( 1 \leq i \leq k \), we have that

\[
m_\ell \oplus \mathbb{R} \text{-span}\{X_{e_1}, \ldots, X_{e_i}\}
\]
is a subalgebra, and so

$$B_\omega(\ell) = \{X_1, \ldots, X_c, Y_{m_1}, Y_{m_2}, \ldots, Y_{m_p}, X_{c_1}, \ldots, X_{c_k}\}$$

is indeed a weak Malcev basis for $n$, as desired.

All that remains to be shown is that the Plancherel measure of $\mathcal{W} \sim \mathcal{W}_S$ is zero, so the strongly generic parametrizing functionals induce almost all of the general position irreducible unitary representations in $\hat{N}$. To this end, let

$$Q(\ell_{d_1}, \ldots, \ell_{d_r}) = (k-1b_{i_k,L_{i_k}}) \times \cdots \times (1b_{i_2,L_{i_2}})(b_{i_1,L_{i_1}}),$$

where the right-hand side is the polynomial in $(SGC \ast)$. If $\ell \in \mathcal{W}_S$, we know that $Q(\ell_{d_1}, \ldots, \ell_{d_r}) \neq 0$. In fact, $\mathcal{W}_S$ is just the Zariski-open set

$$\mathcal{W}_S = \{\ell \in \mathcal{W}: Q(\ell_{d_1}, \ldots, \ell_{d_r}) \neq 0\}.$$ 

Since the zero set of the non-trivial polynomial $Q(\ell_{d_1}, \ldots, \ell_{d_r})$ is at most $(r-1)$-dimensional, we have that

$$m^*_r(\mathcal{W} \sim \mathcal{W}_S) = 0,$$

where $m^*_r$ is $r$-dimensional Lebesgue measure on $\mathcal{W}$. But then the Plancherel measure of $\mathcal{W} \sim \mathcal{W}_S$ is

$$\rho(\mathcal{W} \sim \mathcal{W}_S) = \int_{\mathcal{W} \sim \mathcal{W}_S} |\text{Pfaffian}(\ell)| \, dm^*_r(\ell) = 0,$$

and we are done.†

† If a strong Malcev basis has been fixed for $n$, thus determining the set $\{X_{j_1}, \ldots, X_{j_{2k}}\}$ of orbit vectors, the Pfaffian of the functional $\ell$ is the polynomial function defined by

$$\text{Pfaffian}(\ell)^2 = \det B,$$

where $B_{ik} = B_\ell(X_{j_i}, X_{j_k})$. See [3], pp.150 ff. for further details.
§ 3.1 Still More Background

In proving Conjecture 1.1 for the selected groups \( N \) mentioned in Chapter 1, we shall need to work with the operator-valued Fourier transform of a suitable function \( \varphi \). We begin with a general characterization of this transform (see [2], pp. 206–207).

Let \( \ell \in \mathfrak{n}^* \), and let \( \pi = \pi_\ell \) be the irreducible unitary representation associated with the coadjoint orbit \( \operatorname{Ad}^*(N) \ell \). If \( m \) is any fixed polarization for \( \ell \), we choose a weak Malcev basis \( B_w = \{W_1, \ldots, W_m, U_1, \ldots, U_k\} \) for \( \mathfrak{n} \) which passes through \( m \). Then \( M = \exp(m) \), and \( \Sigma = \exp(\mathbb{R} U_1) \cdots \exp(\mathbb{R} U_k) \) is a closed cross-section of \( M \setminus N \). We recall from Chapter 1 that \( \pi \) may be induced from the character \( \chi = e^{2\pi i \ell \cdot \log} \) on the subgroup \( M \), and that \( \pi \) acts on a Hilbert space \( \mathcal{H}_\pi \) of functions \( f \) on \( N \) that vary like \( \chi \) along \( M \)-cosets, that is, \( f(mn) = \chi(m)f(n) \). The action of \( \pi \) is right-translation: \( \pi(x)f(n) = f(nx) \) for all \( x, n \in N \).

Define polynomial maps

\[
\gamma : \mathbb{R}^n \to N, \quad \alpha : \mathbb{R}^m \to M, \quad \beta : \mathbb{R}^k \to N,
\]
by

\[ \gamma(w,u) = \exp(w_1 W_1 + \cdots + w_m W_m) \exp(u_1 U_1) \cdots \exp(u_k U_k), \]
\[ \alpha(w) = \gamma(w,0), \quad \beta(u) = \gamma(0,u), \]

and let \( dn, dm, \) and \( d\hat{n} \) be the invariant measures on \( N, M, \) and \( M \setminus N \) determined by the Lebesgue measures \( dW \, dU, \) \( dW, \) and \( dU. \) (Of course, \( \alpha \) is just the exponential map on \( m. \) ) Then, using \( d\hat{n} \) in the definition of the norm, \( \|f\|_{H_*}^2 = \int_{M \setminus N} |f|^2 \, d\hat{n}, \) the map sending \( f \to \tilde{f}(u) = f(\beta(u)) \) is an isometry from \( H_\pi \) to \( L^2(\mathbb{R}^k, dU), \) and so \( \pi \) may be modelled as a right action on \( L^2(\mathbb{R}^k). \)

Let \( f \in H_\pi \) be continuous (so \( \tilde{f} \in C(\mathbb{R}^k) \cap L^2(\mathbb{R}^k)). \) Then for suitable functions \( \varphi \) (e.g., \( \varphi \in C_c^\infty(N) \)), the operator

\[ \tilde{\varphi}(\pi)(\cdot) = \int_N \varphi(n) \pi(n)(\cdot) \, dn \]
produces absolutely convergent integrals when applied to \( f. \) Recalling from Chapter 1 that an element \( n \in N \) may be written (uniquely) as the product \( n = m \cdot \beta(u), \) we have the following standard computation:

\[ (\tilde{\varphi}(\pi)(f))(\beta(t)) = \int_N \varphi(n) \pi(n) f(\beta(t)) \, dn \]
\[ = \int_N \varphi(n) f(\beta(t)n) \, dn \]
\[ = \int_N \varphi(\beta(t)^{-1} n) f(n) \, dn \]
\[ = \int_M \int_{\mathbb{R}^k} \varphi(\beta(t)^{-1} m \beta(u)) f(m \beta(u)) \, dm \, du \]
\[ \overset{(5)}{=} \int_{\mathbb{R}^k} \left( \int_M \varphi(\beta(t)^{-1} m \beta(u)) \chi(m) \, dm \right) f(\beta(u)) \, du, \]
where in equation (5) we have used Fubini's theorem and the $\chi$-covariance of $f$. The action of the operator-valued Fourier transform on a function $f$ from the representation space $\mathcal{H}_\pi$ is thus given by the $k$-dimensional integral of the product of $f$ with the kernel function

$$K_\varphi(t,u) = \int_M \varphi(\beta(t)^{-1}m\beta(u)) \chi(m) \, dm.$$ 

§3.2 A Proposition

We may now prove a slightly weakened version\footnote{We assume that $\varphi$ is in $C_c^\infty(N)$, rather than $L_c^\infty(N)$, in order to use the nilpotent Plancherel theorem. The two examples which follow this proposition do not assume that $\varphi$ is smooth.} of Conjecture 1.1 for a large sub-class of nilpotent Lie groups:

3.2 Proposition. Let $N$ be a connected, simply connected nilpotent Lie group with Lie algebra $\mathfrak{n}$, and let $N$ have the property that the set $\mathcal{W} \subset \mathfrak{n}^*$ of linear functionals which parametrize generic coadjoint orbits (with respect to any fixed strong Malcev basis for $\mathfrak{n}$) is polarized by a single maximal subordinate subalgebra $\mathfrak{m}$. Let $\varphi \in C_c^\infty(N)$ and suppose that $\tilde{\varphi}(\pi) = 0$ for all $\pi \in E \subset \bar{N}_{g.p.}$, where the Plancherel measure $\rho(E) > 0$. Then $\varphi \equiv 0$.

Proof. As in Chapter 2, let $B = \{X_1, \ldots, X_n\}$ be a strong Malcev basis which passes through the center $\mathfrak{z}(\mathfrak{n})$ of $\mathfrak{n}$, and let

$$B_w = \{X_1, \ldots, X_c, Y_{m_1}, \ldots, Y_{m_p}, X_{e_1}, \ldots, X_{e_k}\}$$
be the corresponding special weak Malcev basis (note that $Y_{m_2}, \ldots, Y_{m_p}$ do not depend on any elements of $n^*$ in the present case). For convenience in subscripting, let us set $W_1 = X_1, \ldots, W_c = X_c, W_{c+1} = Y_{m_1}, \ldots, W_m = Y_{m_p}$. Now for each $\pi \in E$, there exists a unique $\ell \in \mathcal{W}$ such that $\pi = \pi_\ell$ (Kirillov). Let $E' \subset \mathcal{W}$ correspond to $E \subset \hat{N}_{g,p}$. Then for each $\ell \in E'$, we have (by hypothesis) that $\hat{\varphi}(\pi_\ell) = 0$. Hence for each continuous $f \in \mathcal{H}_{\pi_\ell} \cong \mathcal{H}_{\hat{N}_{g,p}}$, the fixed modelling space for all $\pi \in \hat{N}_{g,p}$, we have, as we saw in §3.1,

$$0 = (\hat{\varphi}(\pi_\ell)f)(\beta(t))$$

$$= \int_{\mathbb{R}^k} \left( \int_M \varphi(\beta(t)^{-1} m \beta(u)) e^{2\pi i \ell (\log m)} dm \right) f(\beta(u)) du$$

for all $t \in \mathbb{R}^k$. Since $C(\mathbb{R}^k) \cap L^2(\mathbb{R}^k)$ is dense in $L^2(\mathbb{R}^k)$, it follows that

$$0 = K_\varphi(t,u,\ell)$$

$$= \int_M \varphi(\beta(t)^{-1} m \beta(u)) e^{2\pi i \ell (\log m)} dm$$

for all $t, u \in \mathbb{R}^k$ and for all $\ell \in E'$.

Now fix $t, u \in \mathbb{R}^k$ arbitrarily, and recall that the set $\{1, \ldots, m\}$ of polarization indices may be viewed as the disjoint union of the sets $D = \{d_1, \ldots, d_r\}$ and $J_I = \{i_1, \ldots, i_k\}$. If $\ell = \sum_{i=1}^r \ell_{d_i} W_{d_i}^* \in E'$ and $W = \sum_{j=1}^m w_j W_j \in \mathcal{M}$, then for all $\ell \in E'$, we have

$$0 = \int_M \varphi(\beta(t)^{-1} m \beta(u)) e^{2\pi i \ell (\log m)} dm$$

$$= \int_{\mathbb{R}^m} \varphi(\beta(t)^{-1} \alpha(W) \beta(u)) e^{2\pi i \ell (\log \alpha(W))} dW$$

$$\overset{(3)}{=} \int_{\mathbb{R}^r} \left( \int_{\mathbb{R}^k} \varphi(\beta(t)^{-1} \alpha(W) \beta(u)) dw_{i_1} \cdots dw_{i_k} \right) \times$$

$$e^{2\pi i (w_{d_1} \ell_{d_1} + \cdots + w_{d_r} \ell_{d_r})} dw_{d_1} \cdots dw_{d_r}.$$
The inner integral in equation (3) is compactly supported and independent of $\ell$. Hence, by the Paley-Wiener theorem, the integral over $\mathbb{R}^r$ extends to an entire function on $\mathbb{C}^r$. Since $E'$ has positive $r$-dimensional measure and the integral vanishes for all $\ell \in E'$, it must in fact vanish for all $\ell \in \mathcal{W}$. Moreover, since $t$ and $u$ were chosen arbitrarily from $\mathbb{R}^k$, we have that the kernel $K_{\varphi}(t, u, \ell)$ vanishes for all $t, u \in \mathbb{R}^k$ and for all $\ell \in \mathcal{W}$. But this is just to say that $\hat{\varphi}(\pi)$ is the zero operator.

So we see that $\hat{\varphi}(\pi) = 0$ for all $\pi \in E'$ implies that $\hat{\varphi}(\pi) = 0$ for all $\pi \in \hat{N}_{g.p.}$. Now by the nilpotent incarnation of the Plancherel Theorem ([3], pp. 144-161), we find that

$$\| \varphi \|_2^2 = \int_{\hat{N}} \text{Tr}(\hat{\varphi}(\pi) \hat{\varphi}(\pi)^*) \, d\rho(\pi) = 0.$$ 

Hence $\varphi \equiv 0$, as desired. $\Box$

We should note that in their paper "Fourier transforms of smooth functions on certain nilpotent Lie groups" [1], Corwin and Greenleaf show that the kernel $K_{\varphi}$ can be rewritten as an exponential factor multiplied by the partial Fourier transform (in the first $m$ variables) of $\varphi \circ \gamma$ composed with a polynomial change of variables map, provided $\varphi \in \mathcal{S}(N)$ and $N$ has the property that every irreducible unitary representation in the support of the Plancherel measure is induced from a single polarizing ideal. They point out that many groups possess this latter property; for example, the $(2n + 1)$-dimensional Heisenberg groups, and the groups of upper triangular $n \times n$ matrices with 1's on the diagonal. Our proposition is slightly more general, in that we do not require the single
polarization to be an ideal, but it is also slightly less general, in that we do not obtain a formula for the kernel \( K_\varphi \), but rather conclude from its vanishing that the compactly supported, infinitely differentiable function \( \varphi \) must also vanish on \( N \). In case the reader wonders whether there are any nilpotent Lie groups with the property assumed in Proposition 3.2, he is referred to the groups labelled \( G_{6,12} \) and \( G_{6,14} \) in Nielsen ([7], pp. 63ff. and pp. 73ff., respectively).

§3.3 Two Examples

We said in Chapter 1 that there are some particular examples of groups lying outside the class just discussed for which Conjecture 1.1 holds as stated. We turn now to two such examples (the writer has dealt similarly with others).

3.3.1 Example. Let \( f_{2,3} \) denote the 3-step free nilpotent Lie algebra on the 2 generators \( X_5 \) and \( X_4 \), and let \( F_{2,3} \) denote the corresponding 1-connected free nilpotent Lie group. A strong Malcev basis for \( f_{2,3} \) is given by \( B = \{ X_1, \ldots, X_5 \} \), with non-zero brackets generated by

\[
[X_5, X_4] = X_3, \quad [X_5, X_3] = X_2, \quad [X_4, X_3] = X_1.
\]

Suppressing central zeros (as in Chapter 2), we may write the augmented matrix \([A_\ell]\) of the bilinear form \( B_\ell \) for \( \ell \in f_{2,3}^* \) as

\[
[A_\ell] = \begin{bmatrix}
0 & -\ell_1 & -\ell_2 & | & X_3 \\
\ell_1 & 0 & -\ell_3 & | & X_4 \\
\ell_2 & \ell_3 & 0 & | & X_5
\end{bmatrix}.
\]
Since row 3 is the first non-central row, we note that $X_3 \in \mathfrak{m}_\ell^3$. Next, we replace $X_3$ by zero in the bookkeeping column, set $\ell_1 \neq 0$, and set $\ell_3 = \ell_4 = 0$. Then, using $\ell_1$ and $-\ell_1$, we row-reduce and antisymmetrize, producing the matrix

$$1[A_\ell] = \begin{bmatrix} 0 & -\ell_1 & 0 & 0 \\ \ell_1 & 0 & 0 & X_4 \\ 0 & 0 & 0 & 1X_5 \end{bmatrix},$$

where $1X_5 = \ell_1X_5 - \ell_2X_4$. The strongly generic parametrizing functionals in $\mathfrak{f}_{2,3}^*$ comprise the set $\mathcal{W}_S = \{ \ell \in \mathfrak{f}_{2,3}^* : \ell_1 \neq 0, \ell_3 = \ell_4 = 0 \}$. A polarization for $\ell \in \mathcal{W}_S$ is given by $\mathfrak{m}_\ell = \mathbb{R} \text{span}\{X_1, X_2, Y_3, Y_5^\ell\}$, where $Y_3 = X_3$ and

$$Y_5^\ell = \frac{1}{\ell_1}1X_5$$

$$= X_5 - \frac{\ell_2}{\ell_1}X_4$$

$$= X_5 + c(\ell)X_4.$$

$\mathfrak{f}_{2,3}$ itself may be written $\mathfrak{m}_\ell \oplus \mathbb{R}X_4$.

We have just seen that many nilpotent Lie algebras have the property that a single ideal polarizes all generic functionals. Although we did not mention it above, such an ideal must also be abelian ([1], p.205). $\mathfrak{f}_{2,3}$ is the lowest dimensional example (and, up to isomorphism, the only 5-dimensional example) to lack this property (see [7], Ch.1). In fact, $\mathfrak{m}_\ell$ is an ideal (as can always be arranged for 3-step algebras), but it is non-abelian and rotates as $\ell$ varies through the set $\mathcal{W}_S$ of strongly generic parametrizing functionals.

To fix notation, let $W(\ell) = w_1X_1 + w_2X_2 + w_3Y_3 + w_5Y_5^\ell$ denote an arbitrary element of the polarization $\mathfrak{m}_\ell$, let $m(\ell) = \exp(W(\ell))$ denote the
corresponding group element, and let \( \beta(t) = \exp(tX_4) \). As Euclidean measure on the polarizations \( m_\ell \) we shall always choose

\[
dW = dw_1 dw_2 dw_3 dw_5,
\]

which is just the fixed Euclidean measure on the projection of \( m_\ell \) onto the hyperplane \( \mathbb{R} \cdot \text{span}\{X_1, X_2, X_3, X_5\} \). As remarked in Chapter 2, this choice of measure is valid for all functionals \( \ell \in \mathcal{W}_S \) (indeed, for all generic functionals in the present example). The measure \( dW \, dx_4 \) on \( f_{2,3} \), with \( dx_4 \) being Lebesgue measure on \( \mathbb{R} \cdot X_4 \), corresponds to the invariant (Haar) measure \( dm(\ell) \, du \) on the group \( F_{2,3} \).

We are now ready to state and prove Conjecture 1.1 for \( F_{2,3} \):

Let \( \varphi \in L^\infty_c(F_{2,3}) \), and suppose that \( \hat{\varphi}(\pi) = 0 \) for all \( \pi \in E \), where \( E \) is a subset of the strongly generic representations in \( \hat{F}_{2,3} \) and \( E \) has positive Plancherel measure. Then \( \varphi = 0 \) almost everywhere on \( F_{2,3} \).

**Proof.** For each \( \pi \in E \), there exists a unique \( \ell \in \mathcal{W}_S \) such that \( \pi = \pi_{\ell} \). Letting \( E' \subset \mathcal{W}_S \) correspond to \( E \subset \hat{F}_{2,3} \), we have by hypothesis that \( \hat{\varphi}(\pi_{\ell}) = 0 \) for all \( \ell \in E' \). Hence, for each continuous \( f \in \mathcal{H}_{\pi_{\ell}} \cong L^2(\mathbb{R}) \), we have (writing \( \tilde{f} \) for the function we earlier called \( \hat{f} \)):

\[
0 = (\hat{\varphi}(\pi_{\ell}) \hat{f})(t) = \int_{\mathbb{R}} \left( \int_{M_{\ell}} \varphi(\beta(t)^{-1} m(\ell) \beta(u)) e^{2\pi i t \left( \log m(\ell) \right)} \, dm(\ell) \right) f(u) \, du
\]

for all \( t \in \mathbb{R} \), and for all \( \ell \in E' \). Since \( C(\mathbb{R}) \cap L^2(\mathbb{R}) \) is dense in \( L^2(\mathbb{R}) \), we must therefore have

\[
0 = \int_{M_{\ell}} \varphi(\beta(t)^{-1} m(\ell) \beta(u)) e^{2\pi i t \left( \log m(\ell) \right)} \, dm(\ell)
\]
for all \( t, u \in \mathbb{R} \), and for all \( \ell \in E' \).

When we reached this point in the proof of Proposition 3.2, we were able to continue by noting that for each fixed choice of \( t, u \in \mathbb{R}^k \), and for all \( \ell \in E' \), we have \( 0 = \int_M \varphi(\beta(t)^{-1} m_\beta(u)) \, e^{2\pi i \ell (\log m)} \, dm \), and so on. But there is an important difference between then and now: the present integral is over \( M_\ell \), not over \( M \). As \( \ell \) varies through \( E' \), \( M_\ell \) will also vary. We must find a new argument for the vanishing of \( \varphi \).

Since we shall need to manipulate the kernel function \( K_\varphi \), we employ the notational conveniences

\[ X \ast Y = \log(\exp(X) \cdot \exp(Y)) \quad \text{(Campbell-Baker-Hausdorff product)} \]

and \( \tilde{\varphi} = \varphi \ast \exp \). Then for any \( \ell \in \mathcal{W}_S \), we have:

\[
K^{\ell}_{\varphi}(t, u) = K_\varphi(t, u, \ell) \\
= \int_{M_\ell} \varphi(\beta(t)^{-1} m(\ell) \beta(u)) \, e^{2\pi i \ell (\log m(\ell))} \, dm(\ell) \\
= \int_{m_\ell} \tilde{\varphi}(-tX_4 \ast W(\ell) \ast uX_4) \, e^{2\pi i \ell (\log(\exp W(\ell)))} \, dW \\
= \int_{m_\ell} \tilde{\varphi}(-tX_4 \ast W(\ell) \ast tX_4 \ast (u - t)X_4) \, e^{2\pi i \ell (W(\ell))} \, dW \\
(5) = \int_{m_\ell} \tilde{\varphi}(W(\ell) \ast (u - t)X_4) \, e^{2\pi i \ell (tX_4 \ast W(\ell) \ast -tX_4)} \, dW \\
= \int_{m_\ell} \tilde{\varphi}(W(\ell) \ast (u - t)X_4) \, e^{2\pi i \text{Ad}^*(\exp -tX_4)^{\ell} (W(\ell))} \, dW,
\]

where in equation (5) we use the fact that \( m_\ell \) is an ideal in \( f_{2,3} \).
Writing \( \tilde{\ell} = \text{Ad}^*(\exp -tX_4)\ell \), we compute that

\[
\tilde{\ell} = \ell + \text{ad}^*(-tX_4)\ell + \frac{1}{2}(\text{ad}^*(-tX_4))^2(\ell)
\]

\[
= \ell_1X_1^* + \ell_2X_2^* + (t\ell_1)X_3^* + (\ell_5 - \frac{1}{2}t^2\ell_1)X_5^*
\]

whence

\[
\tilde{\ell} (W(\ell)) = \ell_1w_1 + \ell_2w_2 + (t\ell_1)w_3 + (\ell_5 - \frac{1}{2}t^2\ell_1)w_5.
\]

Also, using the C-B-H formula, we find that

\[
W(\ell) * (u-t)X_4 = (w_1X_1 + w_2X_2 + w_3X_3 + w_5X_5) * (u-t)X_4
\]

\[
= (w_1X_1 + w_2X_2 + w_3X_3 + w_5X_5 + w_5c(\ell)X_4) * (u-t)X_4
\]

\[
= (w_1X_1 + \cdots + w_5X_5 + w_5c(\ell)X_4) * (-w_5c(\ell))X_4 * (w_5c(\ell))X_4 *(u-t)X_4
\]

\[
\overset{(4)}{=} ((w_1 + P_1)X_1 + (w_2 + P_2)X_2 + (w_3 + P_3)X_3 + w_5X_5) * (u - t + w_5c(\ell))X_4
\]

\[
\overset{(5)}{=} (w_1 + P_1, w_2 + P_2, w_3 + P_3, w_5; u - t + w_5c(\ell)),
\]

where the notational abbreviation in equation (5) is introduced for typographical convenience. The polynomials \( P_1, P_2 \) and \( P_3 \) in equation (4) are easily computed:

\[
P_3 = -\frac{1}{2}w_5^2c(\ell),
\]

\[
P_2 = -\frac{1}{12}w_5^3c(\ell),
\]

\[
P_1 = \frac{1}{2}w_3w_5c(\ell) - \frac{1}{6}w_5^3c(\ell)^2.
\]
Returning to the computation of $K_\varphi^\ell$, we see that

$$K_\varphi(t, u, \ell) \overset{m_\ell}{=} \int_{\mathbb{R}^4} \tilde{\varphi}(W(\ell) * (u - t)X_4) e^{2\pi i \ell \cdot (W(\ell))} dW$$

$$= \int_{\mathbb{R}^4} \tilde{\varphi}(w_1 + P_1, w_2 + P_2, w_3 + P_3, w_5; u - t + w_5 c(\ell)) \times$$

$$e^{2\pi i \left( \ell_1 w_1 + \ell_2 w_2 + (t \ell_1) w_3 + (\ell_5 - \frac{1}{2} t^2 \ell_1) w_5 \right)} dw_1 dw_2 dw_3 dw_5$$

$$\overset{(3)}{=} \int_{\mathbb{R}} \left( \int_{\mathbb{R}^3} \tilde{\varphi}(w_1 + P_1, w_2 + P_2, w_3 + P_3, w_5; u - t + w_5 c(\ell)) \times$$

$$e^{2\pi i \left( \ell_1 w_1 + \ell_2 w_2 + (t \ell_1) w_3 + (-\frac{1}{2} t^2 \ell_1) w_5 \right)} dw_1 dw_2 dw_3 \right) e^{2\pi i (\ell_5 w_5)} dw_5$$

$$= \int_{\mathbb{R}} 1K_\varphi(\ell_1, \ell_2, t, w_5; u - t + w_5 c(\ell)) e^{2\pi i (\ell_5 w_5)} dw_5,$$

where $1K_\varphi(\ell_1, \ell_2, t, w_5; u - t + w_5 c(\ell))$ is a handy (and suggestive) way of referring to the inner 3-dimensional integral on the right-hand side of equation (3).

We observe that this abridged kernel $1K_\varphi(\ell_1, \ell_2, t, w_5; u - t + w_5 c(\ell))$ is independent of $\ell_5$ and compactly supported in the variable $w_5$. Indeed, because of these facts, the hypotheses of the Paley-Wiener theorem for $\mathbb{R}$ are satisfied, and so the integral

$$(*) \int_{\mathbb{R}} 1K_\varphi(\ell_1, \ell_2, t, w_5; u - t + w_5 c(\ell)) e^{2\pi i (\ell_5 w_5)} dw_5$$
defines a function of \( \ell_5 \) (a partial Fourier transform of the abridged kernel) which extends to an entire function on \( \mathbb{C} \). We shall use this fact in a moment.

By hypothesis, for each \( \ell \in E' \), the integral \((*)\) is zero for all \( t, u \in \mathbb{R} \). If we put \( a = u - t + w_5 c(\ell) \), we note that \( a \) can be fixed arbitrarily by simply letting \( u = a + t - w_5 c(\ell) \). In effect, the degree of freedom represented by the variable \( u \) absorbs all variation in \( t, w_5 \) and \( c(\ell) \), thus fixing \( a \). Hence, for each \( \ell \in E' \), the integral \((*)\) is zero for all \( t, a \in \mathbb{R} \). Again, if we set \( \tilde{\ell}_3 = t\ell_1 \), we see that \((*)\) vanishes for all \( \tilde{\ell}_3 \in \mathbb{R} \), using our freedom in \( t \) to vary \( \tilde{\ell}_3 \). So we see that for each \( \ell \in E' \), the integral \((*)\) is zero for all \( \tilde{\ell}_3, a \in \mathbb{R} \).

Let us now consider \( \ell \) to be the ordered triple \((\ell_1, \ell_2, \ell_5)\). Because \( E' \) has positive 3-dimensional measure, there exists a set \( E'_{1,2} \) (say) of positive 2-dimensional measure such that for each pair \((\ell_1, \ell_2) \in E'_{1,2} \), the triple \((\ell_1, \ell_2, \ell_5)\) is an element of \( E' \) for all \( \ell_5 \) in a set \( E'_{5}(\ell_1, \ell_2) \) of positive 1-dimensional measure. (This is a consequence of Fubini's theorem.)

Fix the pair \((\ell_1, \ell_2)\) arbitrarily in the set \( E'_{1,2} \), and then fix \( \tilde{\ell}_3 \) and \( a \) arbitrarily in \( \mathbb{R} \). For all \( \ell_5 \) in the set \( E'_{5}(\ell_1, \ell_2) \), we have that

\[
0 = \int_{\mathbb{R}} K_\varphi(\ell_1, \ell_2, \tilde{\ell}_3, w_5; a) e^{2\pi i (\ell_5 w_5)} \, dw_5.
\]

Because this integral has an entire extension and vanishes on a set of positive 1-dimensional measure, it vanishes for all \( \ell_5 \in \mathbb{R} \). But this vanishing for all \( \ell_5 \) implies, in turn, that

\[
\tilde{\ell}_3 \quad \text{is a kind of ersatz} \quad \ell_3, \text{making up for the absence of the} \quad X_3^- \text{-component in the} \quad \text{strongly generic parametrizing functionals} \quad \ell \text{ with which we are working. We might also point out that, strictly speaking, one ought now to replace every occurrence of} \quad t \text{ in the kernel by} \quad \frac{t a}{\ell_1}.
\]
\[ 0 = K_\phi(\ell_1, \ell_2, \tilde{\ell}_3, w_5 ; a) = e^{2\pi i (-\frac{1}{2} t^2 \ell_1 w_5)} \int_{\mathbb{R}^3} \phi(w_1 + P_1, w_2 + P_2, w_3 + P_3, w_5 ; a) \times e^{2\pi i (\ell_1 w_1 + \ell_2 w_2 + \tilde{\ell}_3 w_3)} \, dw_1 dw_2 dw_3, \]

or, cancelling the non-zero factor \( e^{2\pi i (-\frac{1}{2} t^2 \ell_1 w_5)} \),

\[ 0 = \int_{\mathbb{R}^3} \phi(w_1 + P_1, w_2 + P_2, w_3 + P_3, w_5 ; a) e^{2\pi i (\ell_1 w_1 + \ell_2 w_2 + \tilde{\ell}_3 w_3)} \, dw_1 dw_2 dw_3 \]

for each fixed pair \((\ell_1, \ell_2) \in E_{1,2}'\), and for each fixed choice of \( \tilde{\ell}_3, a, w_5 \in \mathbb{R} \).

Since the polynomial \( P_3 \) does not depend on the remaining variables of integration, the translation invariance of Lebesgue measure implies that sending \( w_3 \to w_3 - P_3 \) in this last integral does not affect its vanishing. Making this replacement and cancelling the resulting non-zero factor \( e^{2\pi i (-\tilde{\ell}_3 P_3)} \), we find that the polynomial \( P_1 \) becomes

\[ 1P_1 = \frac{1}{2} w_3 w_5 c(\ell) + \frac{1}{12} w_5^3 c(\ell)^2, \]

and the last integral above becomes

\[ \int_{\mathbb{R}^3} \phi(w_1 + 1P_1, w_2 + P_2, w_3, w_5 ; a) e^{2\pi i (\ell_1 w_1 + \ell_2 w_2 + \tilde{\ell}_3 w_3)} \, dw_1 dw_2 dw_3 \]

\[ \overset{(1)}{=} \int_{\mathbb{R}} \left( \int_{\mathbb{R}^2} \phi(w_1 + 1P_1, \ldots ; a) e^{2\pi i (\ell_1 w_1 + \ell_2 w_2)} \, dw_1 dw_2 \right) e^{2\pi i \tilde{\ell}_3 w_3} \, dw_3 \]

\[ = \int_{\mathbb{R}} 2K_\phi(\ell_1, \ell_2, w_3, w_5 ; a) e^{2\pi i (\tilde{\ell}_3 w_3)} \, dw_3, \]
where \( 2K_\varphi(\ell_1, \ell_2, w_3, w_5; a) \) refers to the inner 2-dimensional integral in equation (1) above.

This twice-abridged kernel \( 2K_\varphi(\ell_1, \ell_2, w_3, w_5; a) \) is independent of \( \tilde{\ell}_3 \) (and so of \( t \)), and is compactly supported in the variable \( w_3 \). Because of these facts, the integral—call it \((**)*\)—on the right-hand side of equation (1) defines a function of \( \tilde{\ell}_3 \) (a partial Fourier transform of the twice-abridged kernel) which extends to an entire function on \( \mathbb{C} \).

Now we argue almost as before. Fix the pair \((\ell_1, \ell_2) \in E_{1,2}'\), and also fix \( a, w_5 \in \mathbb{R} \). The integral \((**)*\) vanishes for all \( \tilde{\ell}_3 \in \mathbb{R} \), which then implies (again, by Paley-Wiener) that
\[
0 = 2K_\varphi(\ell_1, \ell_2, w_3, w_5; a)
= \int_{\mathbb{R}^2} \varphi(w_1 + P_1, w_2 + P_2, w_3, w_5; a) e^{2\pi i (\ell_1 w_1 + \ell_2 w_2)} \, dw_1 dw_2
\]
for each fixed pair \((\ell_1, \ell_2) \in E_{1,2}'\), and for each fixed \( a, w_3, w_5 \in \mathbb{R} \).

Since the polynomials \( P_1 \) and \( P_2 \) do not depend on the variables \( w_1 \) and \( w_2 \), the translation invariance of Lebesgue measure again assures us that sending \( w_1 \to w_1 - P_1 \) and \( w_2 \to w_2 - P_2 \) in this last integral does not affect its vanishing. Making these replacements and cancelling the resulting non-zero factor \( e^{2\pi i (\ell_1 P_1 - \ell_2 P_2)} \), we find that
\[
0 = \int_{\mathbb{R}^2} \varphi(w_1, w_2, w_3, w_5; a) e^{2\pi i (\ell_1 w_1 + \ell_2 w_2)} \, dw_1 dw_2
\]
for each choice of \( w_3, w_5, a \in \mathbb{R} \), provided the pair \((\ell_1, \ell_2)\) is chosen from the set \( E_{1,2}' \) of positive 2-dimensional measure. But this last integral is just the partial Fourier transform of \( \varphi \) in the central variables \( w_1 \) and \( w_2 \), and so the
fact that it vanishes on $E'_{1,2}$ implies that it vanishes for all pairs $(\ell_1, \ell_2)$. Hence the function $\tilde{\varphi} = \varphi \cdot \exp$ is zero for almost all $w_1, w_2 \in \mathbb{R}$ for each choice of $w_3, w_5, a \in \mathbb{R}$. We see finally, then, that $\varphi = 0$ almost everywhere on $F_{2,3}$, as desired. □
3.3.2 Example. Let $n_7$ denote the 7-dimensional 5-step nilpotent Lie algebra with non-zero brackets generated by

\[[X_7, X_6] = X_5, \quad [X_7, X_5] = X_4, \quad [X_7, X_4] = X_3, \quad [X_7, X_3] = X_2\]
\[[X_6, X_5] = X_3, \quad [X_6, X_4] = X_2, \quad [X_6, X_3] = X_1, \quad [X_5, X_4] = -X_1,\]

and let $N_7$ denote the corresponding 1-connected nilpotent Lie group. Suppressing central zeros, we may write the augmented matrix $[A_\ell]$ of the bilinear form $B_\ell$ for $\ell \in n_7^*$ as

\[
[A_\ell] = \begin{bmatrix}
0 & 0 & 0 & -\ell_1 & -\ell_2 & | & X_3 \\
0 & 0 & \ell_1 & -\ell_2 & -\ell_3 & | & X_4 \\
0 & -\ell_1 & 0 & -\ell_3 & -\ell_4 & | & X_5 \\
\ell_1 & \ell_2 & \ell_3 & 0 & -\ell_5 & | & X_6 \\
\ell_2 & \ell_3 & \ell_4 & \ell_5 & 0 & | & X_7
\end{bmatrix}.
\]

Working as before, we find that the strongly generic parametrizing functionals in $n_7^*$ comprise the set $W_S = \{\ell \in n_7^* : \ell_1 \neq 0, \ell_3 = \ell_4 = \ell_5 = \ell_6 = 0\}$. A polarization for $\ell \in W_S$ is given by $m_\ell = \mathbb{R}\text{-span}\{X_1, X_2, X_3, Y_4, Y_7\}$, where $Y_7^\ell = X_7 - \frac{\ell_4}{\ell_1}X_6 = X_7 + c(\ell)X_6$. The entire algebra $n_7$ may be written as $m_\ell \oplus \mathbb{R}\text{-span}\{X_5, X_6\}$.

The polarization $m_\ell$ for $\ell \in W_S$ is neither abelian nor an ideal. In addition, the two external orbit vectors $X_5$ and $X_6$ do not commute with respect to the Lie bracket; indeed, their bracket $[X_6, X_5] = X_3$ is non-central. In some respects, then, the algebra $n_7$ is more typical than $f_{2,3}$, and so it is interesting to see that our conjecture holds in $n_7$ as well (although the argument is complicated by the fact that $m_\ell$ is not an ideal!).
To fix notation, let \( W(\ell) = w_1X_1 + w_2X_2 + w_3Y_3 + w_4Y_4 + w_7Y_7 \) denote an arbitrary element of the polarization \( m_\ell \), let \( m(\ell) = \exp(W(\ell)) \) denote the corresponding group element, and let \( \beta(u_1, u_2) = \exp(u_1X_5)\exp(u_2X_6) \). As Euclidean measure on the polarizations \( m_\ell \) we shall always choose

\[
dW = dw_1 dw_2 dw_3 dw_4 dw_7,
\]

which is just the fixed Euclidean measure on the projection of \( m_\ell \) onto the hyperplane \( \mathbb{R} \cdot \text{span}\{X_1, X_2, X_3, X_4, X_7\} \). As before, this choice of measure is valid for all functionals \( \ell \in \mathcal{W}_S \). The measure \( dW dx_5 dx_6 \) on \( N_7 \), with \( dx_5 dx_6 \) being Lebesgue measure on \( \mathbb{R} \cdot \text{span}\{X_5, X_6\} \), corresponds to the invariant (Haar) measure \( dm(\ell) du_1 du_2 \) on the group \( N_7 \).

So much being said, we now state and prove Conjecture 1.1 for \( N_7 \):

Let \( \varphi \in L_c^\infty(N_7) \), and suppose that \( \bar{\varphi}(\pi) = 0 \) for all \( \pi \in E \), where \( E \) is a subset of the strongly generic representations in \( \hat{N}_7 \) and \( E \) has positive Plancherel measure. Then \( \varphi = 0 \) almost everywhere on \( N_7 \).

**Proof.** For each \( \pi \in E \), there exists a unique \( \ell \in \mathcal{W}_S \) such that \( \pi = \pi_\ell \). Letting \( E' \subset \mathcal{W}_S \) correspond to \( E \subset \hat{N}_7 \), we have by hypothesis that \( \bar{\varphi}(\pi_\ell) = 0 \) for all \( \ell \in E' \). Hence, for each continuous \( f \in \mathcal{H}_\pi \cong L^2(\mathbb{R}^2) \), we have (again writing \( f \) instead of \( \bar{f} \)):

\[
0 = (\bar{\varphi}(\pi_\ell)f)(t_1, t_2)
= \int_{\mathbb{R}^2} \left( \int_{M_\ell} \varphi(\beta(t_1, t_2)^{-1}m(\ell)\beta(u_1, u_2)) e^{2\pi i t \cdot m(\ell)} dm(\ell) \right) f(u_1, u_2) du_1 du_2
\]
for all \((t_1, t_2) \in \mathbb{R}^2\), and for all \(\ell \in E'\). Since \(C(\mathbb{R}^2) \cap L^2(\mathbb{R}^2)\) is dense in 
\(L^2(\mathbb{R}^2)\), it follows that

\[
0 = \int_{M_t} \varphi(\beta(t_1, t_2)^{-1} m(\ell) \beta(u_1, u_2)) e^{2\pi i \ell \left(\log m(\ell)\right)} \, dm(\ell)
\]

for all \(t_1, t_2, u_1, u_2 \in \mathbb{R}\), and for all \(\ell \in E'\).

Reverting to the notational conveniences \(X \star Y = \log(\exp(X) \cdot \exp(Y))\) and 
\(\tilde{\varphi} = \varphi \cdot \exp\), we have for any \(\ell \in W_S\):

\[
K_{\tilde{\varphi}}(t_1, t_2, u_1, u_2)
= K_{\varphi}(t_1, t_2, u_1, u_2, \ell)
= \int_{M_t} \varphi(\beta(t_1, t_2)^{-1} m(\ell) \beta(u_1, u_2)) e^{2\pi i \ell \left(\log m(\ell)\right)} \, dm(\ell)
= \int_{m_t} \tilde{\varphi}(-t_2 X_6 \star -t_1 X_5 \star W(\ell) \star u_1 X_5 \star u_2 X_6) e^{2\pi i \ell \left(W(\ell)\right)} \, dW.
\]

Our strategy now is to use the Campbell-Baker-Hausdorff formula 'softly' (i.e.,
with little regard for the rational coefficients or their signs) to coax the vector

\[-t_2 X_6 \star -t_1 X_5 \star W(\ell) \star u_1 X_5 \star u_2 X_6\]

into a form more suited to the purposes of our argument. The form we seek is

\[\tilde{W}(\ell, t_1, t_2, u_1 - t_1) \ast (u_1 - t_1 + P_5)X_5 \ast (u_2 - t_2 + P_6)X_6,\]

where

\[\tilde{W}(\ell, t_1, t_2, u_1 - t_1) = (w_1 + P_1)X_1 + \cdots + (w_4 + P_4)X_4 + w_7 X_7\]
and the polynomials $P_1, \ldots, P_6$ have certain special dependencies and non-dependencies which permit our arguments to proceed. For typographical convenience, we shall write $W$ instead of $W(\ell)$ for a while.

We first do the computation in ‘scroll’ mode, without stopping for comments. The underline delineates that part of the product currently being computed, while the overdots on the next line—the ghosts of the departed underlines—identify the results of that computation:

$$- t_2 x_6 * - t_1 x_5 * W * u_1 x_5 * u_2 x_6$$

\[1\] $$- t_2 x_6 * - t_1 x_5 * W * t_1 x_5 * - t_1 x_5 * u_1 x_5 * u_2 x_6$$

\[2\] $$- t_2 x_6 * - t_1 x_5 * W * t_1 x_5 * - t_1 x_5 * u_1 x_5 * u_2 x_6$$

\[3\] $$- t_2 x_6 * 1W * t_2 x_6 * - t_2 x_6 * (u_1 - t_1)x_5 * u_2 x_6$$

\[4\] $$- t_2 x_6 * 1W * t_2 x_6 * - t_2 x_6 * (u_1 - t_1)x_5 * u_2 x_6$$

\[5\] $$2W * - P_6 x_6 * P_6 x_6 * - t_2 x_6 * (u_1 - t_1)x_5 * u_2 x_6$$

\[6\] $$2W * - P_6 x_6 * P_6 x_6 * - t_2 x_6 * (u_1 - t_1)x_5 * u_2 x_6$$

\[7\] $$3W * (- t_2 + P_6)x_6 * (u_1 - t_1)x_5 * -( - t_2 + P_6)x_6 * (- t_2 + P_6)x_6 * u_2 x_6$$

\[8\] $$3W * (- t_2 + P_6)x_6 * (u_1 - t_1)x_5 * -( - t_2 + P_6)x_6 * (- t_2 + P_6)x_6 * u_2 x_6$$

\[9\] $$3W * - P_5 x_5 * P_5 x_5 * S_{5,6} * (u_1 - t_1)x_5 * (u_2 - t_2 + P_6)x_6$$

\[10\] $$3W * - P_5 x_5 * P_5 x_5 * S_{5,6} * (u_1 - t_1)x_5 * (u_2 - t_2 + P_6)x_6$$

\[11\] $$4W * S_{5,6} * (u_1 - t_1 + P_5)x_5 * (u_2 - t_2 + P_6)x_6$$
\[ (12) \quad \frac{4W}{W} * \frac{1}{S_{5,6}} * (u_1 - t_1 + P_5)X_5 * (u_2 - t_2 + P_6)X_6 \]

\[ (13) \quad \frac{5W}{W} * (u_1 - t_1 + P_5)X_5 * (u_2 - t_2 + P_6)X_6. \]

What is going on here is straightforward enough (albeit somewhat tedious to describe). In equations (1), (2) and (3), we 'home' \(-t_1X_5\) across \(W\), producing \(1W\), which is now a \(t_1\)-dependent element of \(m_\varepsilon\). In equations (3), (4) and (5), we bring \(-t_2X_6\) across \(1W\), producing \(2W\), a \(t_1\)- and \(t_2\)-dependent vector which lies \textit{outside} \(m_\varepsilon\) because \([X_7, X_6] = X_5\). (Recall the non-ideality of \(m_\varepsilon\).) In equations (5), (6) and (7)), we remove the \(X_6\)-direction from \(2W\), producing \(3W\). In equations (7), (8) and (9), we home \((-t_2 + P_6)X_6\) across \((u_1 - t_1)X_5\), producing \(S_{5,6}\), a \(t_2(u_1 - t_1)\)-dependent vector containing the directions \(X_1\) and \(X_3\). In equations (9), (10) and (11), we remove the \(X_5\)-direction from \(3W\), producing \(4W\). Also in equations (10) and (11), we home \(P_5X_5\) across \(S_{5,6}\), leaving \(S_{5,6}\) unchanged since \([X_5, X_3] = 0\). Finally, in equations (12) and (13), we multiply \(4W\) on the right by \(S_{5,6}\), producing \(5W\).

Now it is clear, to begin with, that our 'soft' computation has produced a vector of the desired form. Setting \(\tilde{W} = 5W\) gives us

\[
- t_2X_6 * -t_1X_5 * W * u_1X_5 * u_2X_6
\]

\[= \tilde{W}(\ell, t_1, t_2, u_1 - t_1) * (u_1 - t_1 + P_5)X_5 * (u_2 - t_2 + P_6)X_6, \]

where

\[\tilde{W}(\ell, t_1, t_2, u_1 - t_1) = (w_1 + P_1)X_1 + \cdots + (w_4 + P_4)X_4 + w_7X_7.\]

But what about the polynomial coefficients? Ignoring most of the minus signs and also the rational coefficients which are not 1, we claim that
\[ P_6 = w_7c(\ell), \text{ the original coefficient of } X_6 \text{ in } W; \]

\[ P_5 = w_7t_2 + w_7^2c(\ell); \]

\[ P_4 = \sum(\text{monomials in } w_7, c(\ell), t_1, t_2); \]

\[ P_3 = \sum(\text{monomials in } w_7, c(\ell), t_1, t_2, u_1 - t_1); \]

\[ P_2 = -w_4t_2 + w_4w_7c(\ell) + \sum(\text{monomials in } w_7, c(\ell), t_1, t_2); \]

\[ P_1 = -w_3t_2 + w_4t_1 + w_3w_7c(\ell) + w_4 \times \sum(\text{monomials in } w_7, t_2, c(\ell)) \]

\[ + \sum(\text{monomials in } w_7, c(\ell), t_1, t_2, u_1 - t_1) + (u_1 - t_1)t_2^2. \]

In 'proof' of this claim, we offer Table 3.3 (on the next page) and some comments. The table contains all possible ways of decomposing the vectors \( X_1, \ldots, X_7 \) in the strong Malcev basis \( B \) into bracket products of vectors from higher up in the basis. To improve the table's readability, we use a vector's subscript index as its name, and we shall speak accordingly. The zero-th order vectors are just the vectors \( 1, \ldots, 7 \) themselves. The vectors 7 and 6 do not have their own rows in the table because neither can be decomposed into a bracket product—they are the atoms of the algebra. On the other hand, the central vector 1 has thirteen decompositions (thirteen 'names', if you will). The existence of fourth order decompositions of the vectors 1 and 2 indicates that \( n_7 \) is a 5-step Lie algebra.

Table 3.3

Assuming the dependencies of $P_4$ to be clear, let us consider $P_3$. The question is, why does it not depend on the variable $w_4$? Since $w_4$ is the coefficient of $X_4$ in $W$, only the first order bracket $[7,4]$ could conceivably contribute a $w_4$-term to $P_3$ (we are looking now at 3's rectangle in the table). But as we saw in our computation of $\overline{W}$, $w_4X_4$ is never bracketed with $w_7X_7$—hence the absence of $w_4$-terms from $P_3$. A similar argument explains why $P_2$ contains no $w_3$-terms (look at 2's rectangle in the table and note that only $[7,3]$ could contribute a $w_3$, etc.). Again, why does $P_1$ contain only two $w_3$-terms, to wit, the linear term $-w_3t_2$ and the non-linear term $w_3w_7c(\ell)$? Looking at 1's
rectangle, we see that only \([6,3]\) can contribute a term to \(P_1\) containing \(w_3\) as a factor. Now 6 gets bracketed with 3 exactly twice in the computation of \(\bar{W}\): once as \(-t_2X6\) is brought across \(W\), and then again when \(P_6X6\) is removed from \(W\). The first bracketing produces \(-w_3t_2\) and the second produces (up to rational coefficient and sign) \(w_3w_7c(\ell)\). So we see how these arguments go.

Now there are certain kinds of terms which, if they occurred in the polynomials \(P_1, \ldots, P_4\), would spell disaster for the arguments we plan to make. Specifically, these are terms containing factors of the form \(w_4t_1t_2\) or \(w_3t_1t_2\) or \(w_3w_4t_1t_2\) (or \(w_4t_1t^2_2\), etc.). Why do such terms not occur? Why, for example, do no terms containing the factor \(w_4t_1t_2\) occur? The answer is not far to seek: such a factor would have to originate from a non-zero bracket product containing \(X_4, X_5\) and \(X_6\) (recalling that \(-t_1X_5\) and \(-t_2X_6\) are the ultimate sources of factors involving \(t_1\) and \(t_2\)). No such product exists, as a rapid perusal of the table reveals. Similar considerations rule out the other dangerous factors.

We hope that enough has been said to convince the reader of the correctness of the listed dependencies of the polynomials \(P_1, \ldots, P_4\). In the arguments to follow, the linear terms in \(P_1\) and \(P_2\) will play a crucial role, while the remaining, mostly non-linear terms in all of the polynomials will prove a nuisance. We shall have recourse to the foregoing statements of dependencies in order to show that as we integrate out a particular direction, the inner expression (an integral multiplied by an exponential factor) does not vary in undesirable ways. So let us return to the kernel \(K^\ell\). 
Setting \( a_1 = u_1 - t_1 + P_5 \) and \( a_2 = u_2 - t_2 + P_6 \), and noting that
\[
\ell(W) = \ell_1 w_1 + \ell_2 w_2 + \ell_7 w_7,
\]
we now find that
\[
K_\varphi(t_1, t_2, u_1, u_2, \ell)
\]
\[
= \int \varphi(W \ast a_1 X_5 \ast a_2 X_6) e^{2\pi i \ell(W)} dW
\]
\[
= \int_{\mathbb{R}^5} \varphi(w_1 + P_1, \ldots, w_4 + P_4, w_7; a_1, a_2) \times
\]
\[
e^{2\pi i (\ell_1 w_1 + \ell_2 w_2 + \ell_7 w_7)} d w_1 \, d w_2 \, d w_3 \, d w_4 \, d w_7
\]
\[
\overset{(3)}{=} \int_{\mathbb{R}} \left( \int_{\mathbb{R}^4} \varphi(w_1 + P_1, \ldots, w_4 + P_4, w_7; a_1, a_2) \times
\]
\[
e^{2\pi i (\ell_1 w_1 + \ell_2 w_2)} d w_1 \, d w_2 \, d w_3 \, d w_4 \right) e^{2\pi i (\ell_7 w_7)} d w_7
\]
\[
= \int_{\mathbb{R}} 1K_\varphi(\ell_1, \ell_2, t_2, t_1, w_7; a_1, a_2) e^{2\pi i (\ell_7 w_7)} d w_7,
\]
where \( 1K_\varphi(\ell_1, \ell_2, t_2, t_1, w_7; a_1, a_2) \) refers to the inner 4-dimensional integral on
the right-hand side of equation (3).

We observe that this abridged kernel \( 1K_\varphi(\ell_1, \ell_2, t_2, t_1, w_7; a_1, a_2) \) is independent of \( \ell_7 \) and compactly supported in the variable \( w_7 \). Because of these facts, the Paley-Wiener theorem implies that the integral
\[
(*) \int_{\mathbb{R}} 1K_\varphi(\ell_1, \ell_2, t_2, t_1, w_7; a_1, a_2) e^{2\pi i (\ell_7 w_7)} d w_7,
\]
defines a function of \( \ell_7 \) (a partial Fourier transform of the abridged kernel) which
extends to an entire function on \( \mathbb{C} \).
By hypothesis, the integral (*) is zero for all \( t_1, t_2, u_1, u_2 \in \mathbb{R} \) and for all \( \ell \in E' \). Since we have put \( a_1 = u_1 - t_1 + P_5 \) and \( a_2 = u_2 - t_2 + P_6 \), we note that \( a_1 \) and \( a_2 \) can be fixed arbitrarily by letting \( u_1 = a_1 + t_1 - P_5 \) and \( u_2 = a_2 + t_2 - P_6 \), respectively. Hence, the integral (*) is zero for all \( t_1, t_2, a_1, a_2 \in \mathbb{R} \) and for all \( \ell \in E' \).

Let us now consider \( \ell \) to be the ordered triple \((\ell_1, \ell_2, \ell_7)\). Because \( E' \) has positive 3-dimensional measure, there exists a set \( E'_{1,2} \) of positive 2-dimensional measure such that for each pair \((\ell_1, \ell_2) \in E'_{1,2}\), the triple \((\ell_1, \ell_2, \ell_7)\) is an element of \( E' \) for all \( \ell_7 \) in a set \( E'_7(\ell_1, \ell_2) \) of positive 1-dimensional measure. (This is, as before, a consequence of Fubini's theorem.)

Fix \( t_1, t_2, a_1, a_2 \in \mathbb{R} \) arbitrarily and fix the pair \((\ell_1, \ell_2)\) arbitrarily in the set \( E'_{1,2} \). Then for all \( \ell_7 \) in the set \( E'_7(\ell_1, \ell_2) \), the integral (*) vanishes. Its possession of an entire extension then implies its vanishing for all \( \ell_7 \in \mathbb{R} \). But this vanishing for all \( \ell_7 \) implies, in turn, that

\[
0 = \frac{1}{2\pi i} K_\phi(\ell_1, \ell_2, t_1, t_2, w_7; a_1, a_2)
\]

\[
\int_{\mathbb{R}^4} \hat{\phi}(w_1 + P_1, w_2 + P_2, w_3 + P_3, w_4 + P_4, w_7; a_1, a_2) \times e^{2\pi i (\ell_1 w_1 + \ell_2 w_2)} dw_1 dw_2 dw_3 dw_4
\]

for each fixed choice of \( t_1, t_2, a_1, a_2 \in \mathbb{R} \) and, given any fixed pair \((\ell_1, \ell_2) \in E'_{1,2}\), for each fixed \( w_7 \in \mathbb{R} \).

The integral in equation (2) is taken over the four variables \( w_1, \ldots, w_4 \), but the exponential factor contains only the variables \( w_1 \) and \( w_2 \). The missing \( w_3 \) and \( w_4 \) variables must in fact be carried upstairs from the argument of the function \( \hat{\phi} \) by a change of variables. First, we send \( w_4 \mapsto w_4 - P_4 \). We saw
above that $P_3$ does not depend on $w_4$; hence this translation alters only $P_1$ and $P_2$, which become

$$1P_2 = -w_4 t_2 + w_4 w_7 c(\ell) + \sum (\text{monomials in } w_7, c(\ell), t_1, t_2)$$
$$+ P_4 t_2 - P_4 w_7 c(\ell),$$

$$1P_1 = -w_3 t_2 + w_3 w_7 c(\ell) + w_4 t_1 + w_4 \times \sum (\text{monomials in } w_7, t_2, c(\ell))$$
$$+ \sum (\text{monomials in } w_7, c(\ell), t_1, t_2, u_1 - u_1) + (u_1 - u_1) t_2^2$$
$$- P_4 t_1 - P_4 \times \sum (\text{monomials in } w_7, t_2, c(\ell)).$$

The underlined terms of these two polynomials do not depend on the remaining variables of integration. Thus, sending

$$w_1 \mapsto w_1 - \text{(the underlined terms in } 1P_1)$$

produces an exponential factor which can be removed from the integrand and then cancelled (since the integral in equation (2) vanishes for the values of the variables with which we are concerned). A similar thing happens if we send

$$w_2 \mapsto w_2 - \text{(the underlined terms in } 1P_2).$$

So let us consider these two additional translations and subsequent cancellations as having been made, producing the more manageable polynomials

$$2P_2 = -w_4 t_2 + w_4 w_7 c(\ell)$$

$$2P_1 = -w_3 t_2 + w_3 w_7 c(\ell) + w_4 t_1 + w_4 \times \sum (\text{monomials in } w_7, t_2, c(\ell)).$$

If we now also send $w_3 \mapsto w_3 - P_3$, we find that $2P_2$ does not change, but
\[ 3P_1 = -w_3 t_2 + w_3 w_7 c(\ell) + w_4 t_1 + w_4 \times \sum (\text{monomials in } w_7, t_2, c(\ell)) \]
\[ + P_3 t_2 - P_3 w_7 c(\ell). \]

Again, the underlined terms do not depend on \( w_1, \ldots, w_4 \). Repeating the procedure of a moment ago, we send
\[ w_1 \mapsto w_1 - (\text{the underlined terms in } 3P_1) \]
and cancel the resulting exponential factor, producing the polynomial
\[ 4P_1 = -w_3 t_2 + w_3 w_7 c(\ell) + w_4 t_1 + w_4 \times \sum (\text{monomials in } w_7, t_2, c(\ell)), \]
which is identical with \( 2P_2 \).

Before we can continue our integrations, we must finish the task of bringing the variables \( w_3 \) and \( w_4 \) up into the exponential \( e^{2\pi i (\ell_1 w_1 + \ell_2 w_2)} \). To this end, we make our final changes of variables, sending \( w_1 \mapsto w_1 - 4P_1 \) and \( w_2 \mapsto w_2 - 2P_2 \). The integral that we last saw in equation (2) now has the form
\[
\int_{\mathbb{R}^4} \tilde{\varphi}(w_1, w_2, w_3, w_4, w_7; a_1, a_2) e^{2\pi i Q} e^{2\pi i (\ell_1 w_1 + \ell_2 w_2 + \ell_3 w_3 + \ell_4 w_4)} dw_1 dw_2 dw_3 dw_4
\]
\[
= \int_{\mathbb{R}^3} e^{2\pi i Q_4} \left( \int_{\mathbb{R}^3} \tilde{\varphi}(w_1, w_2, w_3, w_4, w_7; a_1, a_2) e^{2\pi i Q_3} \right. \\
\times \\
\left. e^{2\pi i (\ell_1 w_1 + \ell_2 w_2 + \ell_3 w_3)} dw_1 dw_2 dw_3 \right) e^{2\pi i (\ell_4 w_4)} dw_4,
\]
where we have introduced the abbreviations:
\[
\begin{align*}
\tilde{\ell}_3 &= t_2 \ell_1 \\
\tilde{\ell}_4 &= t_2 \ell_2 - t_1 \ell_1 \\
Q &= Q_3 + Q_4 \\
&= w_3(-w_7 \ell_1 c(\ell)) + w_4(-w_7 \ell_2 c(\ell) + (\text{terms in } w_7, t_2, c(\ell))).
\end{align*}
\]

The polynomial \( Q \) contains the remnants of the non-linear terms from the argument of \( \tilde{\varphi} \), \( Q_3 \) containing the single \( w_3 \)-term and \( Q_4 \) containing the \( w_4 \)-terms. \( \tilde{\ell}_3 \) and \( \tilde{\ell}_4 \) are now the third and fourth components, respectively, of the strongly generic parametrizing functionals in \( E' \). For future reference, we point out that the variable \( t_1 \) does not appear in \( Q \), and the variable \( t_2 \) appears only in \( Q_3 \).

Consider now the linear system
\[
\begin{cases}
\tilde{\ell}_3 = t_2 \ell_1 \\
\tilde{\ell}_4 = t_2 \ell_2 - t_1 \ell_1.
\end{cases}
\]

Since \( \ell \) is strongly generic, which in this example means that \( \ell_1 \neq 0 \), we may solve for \( t_2 \) in the top equation of this system, and then substitute in the bottom equation, obtaining
\[
\tilde{\ell}_4 = \frac{\tilde{\ell}_3}{\ell_1} \ell_2 - t_1 \ell_1 = -\tilde{\ell}_3 c(\ell) - t_1 \ell_1.
\]

If we fix the pair \( (\ell_1, \ell_2) \in E_{1,2}' \) and also fix \( t_2 \in \mathbb{R} \), we see that \( \tilde{\ell}_3 \) is also fixed, but \( \tilde{\ell}_4 \) may be varied \textit{ad libitum} by varying \( t_1 \).
What this means is that if we write

$$
\int_{\mathbb{R}} \left( \int_{\mathbb{R}^3} e^{2\pi i Q_4} \, \hat{\varphi}(w_1, w_2, w_3, w_4, w_7; a_1, a_2) \, e^{2\pi i Q_3} \times \right.
$$

$$
e^{2\pi i (\ell_1 w_1 + \ell_2 w_2 + \ell_3 w_3)} \, dw_1 dw_2 dw_3 \bigg) \, e^{2\pi i \ell_4 w_4} \, dw_4
$$

$$
= \int_{\mathbb{R}} 2K_{\tilde{\varphi}}(\ell_1, \ell_2, \tilde{\ell}_3, w_4, w_7; a_1, a_2) \, e^{2\pi i \tilde{\ell}_4 w_4} \, dw_4,
$$

where $2K_{\tilde{\varphi}}(\ell_1, \ell_2, \tilde{\ell}_3, w_4, w_7; a_1, a_2)$ denotes the parenthesized expression on the right-hand side of the first equation, then this twice-abridged kernel is independent of $\ell_4$ (which is another way of saying that varying $t_1$ does not shift the kernel), and it is also compactly supported in the variable $w_4$. The Paley-Wiener theorem again tells us that the integral

$$(**)
\int_{\mathbb{R}} 2K_{\tilde{\varphi}}(\ell_1, \ell_2, \tilde{\ell}_3, w_4, w_7; a_1, a_2) \, e^{2\pi i \tilde{\ell}_4 w_4} \, dw_4$$

defines a function of $\tilde{\ell}_4$ (a partial Fourier transform of the twice-abridged kernel) which extends to an entire function on $\mathbb{C}$.

Having travelled this route before, we know what comes next. For each fixed pair $(\ell_1, \ell_2) \in E'_{1,2}$, and for each fixed choice of $\tilde{\ell}_3, w_7, a_1, a_2 \in \mathbb{R}$, the integral $(**)$ vanishes for all $\tilde{\ell}_4 \in \mathbb{R}$. The existence of an entire extension of $(**)$ then implies the vanishing of $2K_{\tilde{\varphi}}(\ell_1, \ell_2, \tilde{\ell}_3, w_4, w_7; a_1, a_2)$ for all $w_4 \in \mathbb{R}$ (under the same hypotheses). We remark that $e^{-2\pi i Q_4}(2K_{\tilde{\varphi}})$ also vanishes, and so we cancel the exponential containing $Q_4$. 

One more rewrite of the remaining integral puts us where we want to be:

\[
\int_{\mathbb{R}^8} \tilde{\varphi}(w_1, w_2, w_3, w_4, w_7; a_1, a_2) e^{2\pi i Q} e^{2\pi i (\ell_1 w_1 + \ell_2 w_2 + \ell_3 w_3)} \, dw_1 dw_2 dw_3
\]

\[
= \int_{\mathbb{R}} \left( e^{2\pi i Q_3} \int_{\mathbb{R}^2} \tilde{\varphi}(w_1, w_2, w_3, w_4, w_7; a_1, a_2) \times \right.
\]

\[
e^{2\pi i (\ell_1 w_1 + \ell_2 w_2)} \, dw_1 dw_2 \left. e^{2\pi i (\ell_3 w_3)} \right) \, dw_3.
\]

It is clear that the parenthesized expression \(3K\tilde{\varphi}\) (as we should call it) is independent of \(\ell_3\), that the whole integral, considered as a function of \(\ell_3\), has an entire extension to \(\mathbb{C}\) (Paley-Wiener), and that under hypotheses identical to those above (supplemented by the additional freedom in \(w_4\)), the vanishing of the whole integral for all \(\ell_3 \in \mathbb{R}\) implies the vanishing of \(e^{-2\pi i Q_3 (3K\tilde{\varphi})}\) for each fixed pair \((\ell_1, \ell_2) \in E'_{1,2}\) and for each choice of \(w_3, w_4, w_7, a_1, a_2 \in \mathbb{R}\).

Under these last hypotheses, we now have that

\[
0 = \int_{\mathbb{R}^2} \tilde{\varphi}(w_1, w_2, w_3, w_4, w_7; a_1, a_2) e^{2\pi i (\ell_1 w_1 + \ell_2 w_2)} \, dw_1 dw_2.
\]

Since this integral is the partial Fourier transform of \(\tilde{\varphi}\) in the central variables \(w_1\) and \(w_2\), and since it vanishes for all pairs \((\ell_1, \ell_2)\) in a set of positive 2-dimensional measure, it vanishes for all pairs \((\ell_1, \ell_2)\). Hence the function \(\tilde{\varphi} = \varphi \ast \exp\) on \(n_7\) vanishes for almost all \(w_1, w_2 \in \mathbb{R}\) and for all \(w_3, w_4, w_7, a_1, a_2 \in \mathbb{R}\). So we see, finally, that \(\varphi = 0\) almost everywhere on \(N_7\), as desired. \(\square\)
Bibliography

Vita

James Donald Moss, Jr. was born on January 9, 1952 in Natchitoches, Louisiana. In May of 1973, he was graduated from Centenary College of Louisiana with a B.A. in Philosophy. In May of 1986, he was graduated from the Louisiana State University with an M.S. in Mathematics. In August of 1991, he was graduated from the Louisiana State University with a Ph.D. in Mathematics.
Candidate: James Donald Moss, Jr.

Major Field: Mathematics

Title of Dissertation: On the Construction and Application of Certain Special Polarizations in Nilpotent Lie Algebras

Approved:
